Abstract: *The conundrum of post-psychotic depression (PPD) is still present in the psychiatric literature, for more than a century since it was first described by Mayer-Gross. After a short existence in the DSM-IV and ICD-10, this nosological construct was excluded from newer versions of the mental disorders classifications. Therefore, an exploratory analysis of the PPD concept was considered useful both from clinical and theoretical perspectives. There is a high prevalence of depressive symptoms in patients with schizophrenia spectrum disorders (SSD) and, although not all of them represent cases of PPD, they are considered risk factors for suicide. The arguments and contra-arguments for/against PPD were reviewed, and the potential pharmacological interventions for this disorder were analyzed. The explored evidence indicates that PPD is worth further investigation, and in order to differentiate it from schizoaffective disorder, negative symptoms of SSD, or depressive manifestations within the acute psychotic episodes, clearly defined criteria should be found. The use of validated scales, like the Calgary Depression Scale for Schizophrenia and the InterSePT Scale for Suicidal Thinking, is recommended for the initial assessment of depression and suicidal risk in patients with SSD, but also for their monitoring during the acute and maintenance phases. Besides the administration of combined, antidepressant and antipsychotic treatment, the use of clozapine, and the recommendation to initiate treatment for SSD with atypical antipsychotics whenever possible, there is a dearth of studies exploring specific interventions for PPD. Future studies are expected to address the validity of the nosological construct of PPD and the most adequate therapeutic and prophylactic interventions in patients with SSD.*

Keywords: *post-psychotic depression, schizophrenia spectrum disorders, atypical antipsychotics, clozapine, typical anti-psychotics, antidepressants*

INTRODUCTION

Depression that may appear in the context of schizophrenia is considered a complex and heterogeneous group of disorders [1,2]. Mayer-Gross was the first author who described in 1920 the reaction to a psychotic experience that manifests itself as a clinical version of depression [3]. He considered "despair" as the main clinical characteristic of this depression that follows a full-blown psychotic episode, and considered this manifestation to be determined by the patient's increased awareness about the severity of his/her illness [3,4]. A few decades later, Semrad also explored the psychodynamic mechanisms for post-psychotic depression (PPD), emphasizing the denial, projection, and distortion of reality after the remission of acute psychotic episodes [5]. PPD was described by several authors as "retarded depression, with strong neurasthenic and schizoid components" emerging after the patient is discharged from the hospital, and often ignored by mental health specialists [6]. Depressive manifestations in patients with SSD have been conceptualized as a psychological reaction to acute psychosis, as previously mentioned, but also as a comorbidity of two distinct pathologies or a proof for the existence of a continuum between schizophrenia and mood disorders [2]. According to psychoanalysts, PPD is a reaction to psychosis, which appears after the remission of the psychotic episode, more specifically, after the Ego regained a significant proportion of its strengths [7,8].

Some authors, however, reported, based on the analysis of the temporal relationship between the onset of depressive and psychotic symptoms in 27 patients, that the first reports on mood manifestations were frequently at the same time same as the onset of psychosis [9]. Therefore, PPD is a controversial concept, as no specific pattern for its onset could be detected, leading to the assumption that depressive manifestations may be only associated with acute psychotic manifestations.

However, a series of studies focused on PPD have tried to delineate the risk factors, clinical features, and prognosis of this nosological entity, as a distinctive pathology from depressive symptoms belonging to acute schizophrenia, mood episodes within a schizoaffective disorder, or adverse events of the antipsychotics or other drugs. For example, a comparison of patients with schizophrenia presenting or not with PPD (N=30 participants in each group) showed that belonging to elementary (or nuclear) families, longer duration of psychotic phase, more frequent hospitalizations, and more sadness and anxiety-somatization during the acute phase of the disease were associated with PPD [10]. A past history of depression was also more frequently reported in the study group vs. controls [10]. Age of onset, sadness during the acute psychosis phase, premorbid adjustment, social support, and life events were significant determinants of severity for PPD, according to the multiple regression analysis [10].

A cohort study with a 10-year follow-up compared the evolution of 29 patients with schizophrenia and PPD vs. only schizophrenia [11]. Patients with PPD presented at an older age with the onset of schizophrenia and more auditory hallucinations; also, they were admitted more often, but their hospitalizations were of shorter duration [11].

A study that explored the main clinical differences between primary depression (N1= 98 patients) and PPD (N2= 71 patients) concluded that depressed mood, reduced energy, and pathological guilt were more frequently detected in patients with primary depression, while sleep disturbance and ideas of reference with a theme of guilt were more consistently associated with PPD [1].

The duration of PPD was estimated by different authors as varying between several days to several months [12], or, more specifically, between 2 and 26 weeks [8].

Depressive symptoms during a psychotic episode may be as frequent as 50%, and they may correlate with the frequency of relapses, defined by re-admission rate and total length of inpatient treatment [13]. By comparison, the prevalence of PPD reported in the literature was around 30-36% [14,15]. Higher rates of PPD were reported in patients with a first episode of psychosis (FEP), up to 50% [3,15]. Older age, a higher familial load of psychoses, a longer duration of untreated psychosis, the presence of an FEP, and a higher number of stressful life events were associated with a higher risk of PPD [14]. Depression was reported by patients with FEP as being linked to the psychotic experience and to the process of recovering from this experience [16]. Feelings of shame, doubt, and embarrassment, but also loss and social isolation, were associated with the presence of the psychotic experience [16]. Also, the onset of PPD has been correlated to the existence of positive symptoms during acute schizophrenia, especially delusions and hallucinations [17]. A study that enrolled 44 patients (aged 10-40 years) with schizophrenia, all of them during their first six months of the illness, explored the risk of developing PPD one year after discharge from the hospital [18]. Four patients were diagnosed with depression in this interval, according to a Hamilton Depression Rating Scale (HAMD) score ≥17 [18]. Only one case recovered from PPD completely during the follow-up [18]. All patients in this trial were undergoing phenothiazine treatment throughout the monitoring period [18].

In a longitudinal study, 17 patients with schizophrenia were monitored for 6 months, using the 18-item Profile for Rating Depressive and Schizophrenic Behavior (PRDSB) [19]. After recovering from acute psychosis, only 2 participants developed major depressive syndrome [19]. However, over 40% of these patients were interviewed only by telephone after their discharge, so a potential bias regarding the sensitivity of the assessment method can not be excluded [19]. Also, the ethnic homogeneity of the study group could be construed as another potential bias that limits the generalizability of the results.

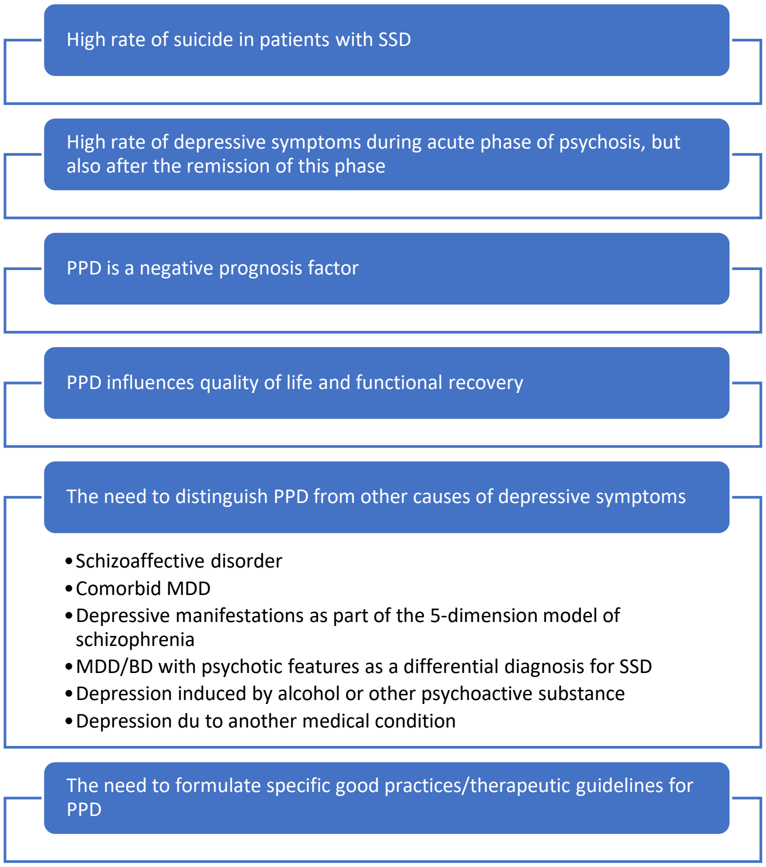
A longitudinal, observational study (N=105 patients with schizophrenia) reported during 12 months of monitoring that depression accompanied acute psychosis in 70% of cases, and remitted together with psychosis, while PPD appeared in 36% of these patients, without a concomitant increase in psychotic symptoms [20].

Focusing the analysis of the PPD concept on the most renowned classifications of mental disorders, this pathology was mentioned for the first time in the Diagnostic and Statistical Manual of Mental Disorders, 4th edition (DSM-IV), published in 1994 [21]. PPD, according to the cited source, involves the presence of "a Major Depressive Episode that is superimposed on and occurs only during the residual phase of schizophrenia" [21]. The definition of PPD required in the DSM-IV the presence of depressed mood, as a core symptom, and excluded the direct consequences of drug abuse, medication use, or a general medical condition [21]. However, in the fifth edition of the DSM, published in 2013, this nosological entity no longer appears [22].

The tenth edition of the International Classification of Diseases, edited by the World Health Organisation (ICD-10) in 1993, grouped PPD (named "post-schizophrenic depression") together with different types of schizophrenia, in the same chapter, coded F20 [23]. The definition of PPD was "a depressive episode, which may be prolonged, arising in the aftermath of a schizophrenic illness" [29]. It is important, according to the ICD-10, that residual schizophrenic symptoms still be present, although they cannot dominate the clinical status [23]. Newer versions of ICD-10 placed PPD in the category of "other specified depressive episodes" [24]. The latest edition of ICD (ICD-11), the first version published in 2019, did not reference PPD [25].

The convoluted trajectory of the PPD concept from its genesis to the present day is rather difficult to explain, but several important factors contributing to this conundrum represent the main objective of the current review (Figure 1).

Figure 1: Rationale for exploring post-psychotic depression



High rate of suicide in patients with SSD

High rate of depressive symptoms during acute phase of psychosis, but also after the remission of this phase

PPD is a negative prognosis factor

PPD influences quality of life and functional recovery

The need to distinguish PPD from other causes of depressive symptoms

- Schizoaffective disorder
- Comorbid MDD
- Depressive manifestations as part of the 5-dimension model of schizophrenia
- MDD/BD with psychotic features as a differential diagnosis for SSD
- Depression induced by alcohol or other psychoactive substance
- Depression du to another medical condition

The need to formulate specific good practices/therapeutic guidelines for PPD

PPD= postpsychotic depression, SSD= schizophrenia spectrum disorders, MDD= major depressive disorder

The rationale for conducting this review derives from several important clinical and theoretical aspects. First, it is essential to obtain adequate control over depressive symptoms in patients with SSD, because of the high rates of suicide reported in this population [26]. PPD seems to be a factor for negative prognosis in the long-term for patients with schizophrenia, especially because of the higher risk for suicide, but also due to its significant impact on the quality of life and general well-being [17]. Second, the need to delineate clinically PPD from other causes of depression in patients with SSD, in order to find the most adequate therapeutic strategies. To support this, the data presented suggest that PPD is a distinct nosological entity from antipsychotic-induced adverse events, negative symptoms of schizophrenia, depression with psychotic symptoms, or schizoaffective disorders [14,17]. This means that good clinical practices in patients with SSD would involve differentiating between PPD and other frequently reported confounding factors.

THE MULTIFACETED CONSTRUCT OF PPD

Although the history of PPD has been over a century, there is a dearth of good-quality studies exploring this pathology's clinical and epidemiological aspects. However, an analysis of the main dimensions of the PPD construct can be done, based on the available evidence (Table 1).

Table 1: Pros and cons in the analysis of the PPD construct

Pros	Cons
PPD was associated with any type of antipsychotic treatment, therefore it is not an adverse event to the first generation antipsychotics	PPD does not exist because it consists of adverse effects of older antipsychotics
There are longitudinal studies that confirm the persistence of depressive symptoms after the remission of acute psychosis and cases where depression followed a period of psychosis remission	The construct should not be treated as a distinct entity, it only accompanies acute schizophrenia
Negative symptoms and depression do not overlap to the point they are indistinguishable	Negative symptoms cover the presence of depression, therefore depression may be observed only after the remission of those symptoms
There are specific scales for measuring depression in patients with SSD, as well as their suicide risk	PPD can not have its own diagnosis criteria and its severity can not be determined, due to the fact that it is secondary to other symptoms

To begin with the presentation of the reasons why PPD is not yet a fully recognized diagnosis, it must be specified that PPD was correlated by different authors with the effects of first-generation antipsychotics, and they called this phenomenon "pharmacological depression" [27-29]. In a multicenter study (N=211 patients with schizophrenia), depression (quantified with HAMD) was detected in 25% of the cases, all of them treated with fluphenazine (either hydrochloride or decanoate) [30]. This study also showed that depression was associated with a more chronic psychiatric history and a higher rate of relapse [30]. Also, older drugs used to treat SSD, such as chlorpromazine or reserpine, have been associated with lethargy, psychomotor retardation, and anergy, which are acknowledged adverse events of these agents [30].

Secondly, the negative symptoms of schizophrenia may cover the depressive symptoms, making them more difficult to detect [14,17]. Anhedonia, defined as a reduced ability to experience pleasant emotions, is considered both a negative symptom in SSD, and a central manifestation in major depressive disorder (MDD) [31-34]. Therefore, it is considered "a transdiagnostic symptom", and its explained by dysfunctions of the reward and aversion pathways in the central nervous system (CNS) [31]. Furthermore, negative symptoms like alogia and avolition may prevent the detection of depressive symptoms, because they interfere with both the interview and the observation of the patients.

The third aspect refers to a contradiction: although current diagnostic classifications do not include mood symptoms in the core criteria for schizophrenia, these are frequently considered part of the clinical picture, as additional manifestations [35]. According to the five-dimension model of schizophrenia, depression is a core clinical component, together with the positive, negative, agitation-excitement, and disorganization symptoms [36]. However, as mentioned in the introductory chapter, there is no reference to PPD in the latest versions of the ICD or DSM [22,25].

The fourth facet of the PPD controversy is represented by the fact that although differentiating between schizophrenia, schizoaffective disorder, and depressive/bipolar disorder with psychotic features is quintessential, in clinical practice it is frequently difficult to make the right diagnosis. Factorial analysis using validated instruments for psychosis and mood symptoms measurement (e.g., Positive and Negative Syndrome Scale – PANSS, Young Mania Rating Scale – YMRS, Montgomery Depression Rating Scale – MADRS, and Calgary Depression Scale – CDSS) confirmed the existence of very complex structure of the clinical manifestations in patients with schizophrenia [37]. Subclinical mood symptoms have been confirmed by this type of analysis, structured within up to 15 factors – e.g., positive, negative, somatic, anxiety, neurocognitive, disorganization and manic, depressive, psychomotor agitation, hostility/violence [37]. These results support the overlapping model of phenotypes between psychotic mood disorders and SSD, and the possibility of misdiagnosing a patient with a mood disorder and associated psychotic features as having an SSD [37].

However, each of these confounding factors may be addressed. The first argument is precarious because even SSD patients treated with newer antipsychotics may develop depressive symptoms and the effect of these pharmacological agents on depressive symptoms is only small to medium [38]. According to a Cochrane review, based on five reports about patients diagnosed with both schizophrenia and depression, there was no significant difference in efficacy (evaluated by PANSS scores) between quetiapine and haloperidol, sulpiride was significantly superior to chlorpromazine (reflected in the severity of depressive symptoms), and clozapine was superior to the association of another antipsychotic and an antidepressant (moclobemide/mianserin) [39]. A significant reduction of depressive symptoms in patients with schizophrenia was reported only if a CDSS score at baseline was ≥5, unlike the positive, negative, and general symptoms (scored with PANSS), in a naturalistic study that enrolled adult patients with ≥2 years of treatment with clozapine (N=23) or other atypical antipsychotics (N=23) [40]. At the follow-up visit, patients who received other antipsychotics led o superior results when compared to clozapine on depressive symptoms, but only when the analysis was limited to those with clinically relevant depression [40]. It can easily be deduced that the results of studies exploring the impact of antipsychotics on depressive symptoms in SSD are quite heterogenous, varying from no difference in outcomes between typicals and atypicals, to superiority of clozapine vs. other antipsychotics combined with antidepressants, and to superiority of other atypicals to clozapine, but only in certain subpopulations.

The second argument is even more difficult to support because authors exploring PPD showed that this syndrome “is usually stable phenomenologically, often lengthy, and may be resistant to all treatment modalities” [6]. Even considering the last part as an exaggeration determined by the lack of adequate therapeutic resources when that statement was formulated, there is still enough ground to back up an independent syndrome, with pharmacological and clinical peculiarities. There are authors that contradict the third argument, stating that depression is “a frequent comorbidity in the course of schizophrenia” [7], and not just a cluster of symptoms intrinsic to SSD.

The fourth argument can also be easily disqualified because there are validated instruments, currently in clinical use, that allow for the monitoring of depressive symptoms in patients with SSD. CDSS is an instrument created by Addington et al., first published in 1990, for the purpose of measuring depression in SSD, starting from selected items within HAMD and Present State Examination (PSE) [41]. This instrument was validated on 50 patients with acute psychosis, and it has 11 items, with a Cronbach’s alpha of 0.84-0.89 [41,42]. The validity of CDSS in evaluating mood symptoms in patients with SSD was confirmed by subsequent studies and reviews, and this scale was significantly correlated with HAMD and MADRS [43,44]. CDSS differentiated depressive symptoms from other clinical manifestations of SSD and also had good predictive validity [44]. Another study comparing CDSS and HAMD (N=119 in-patients with acute schizophrenia) concluded that CDSS had a higher sensitivity than HAMD in assessing mild or severe depression, while the specificity was comparable high for both instruments [45].

The InterSePT Scale for Suicidal Thinking (ISST) has 12 items and was created to assess suicidal ideation in SSD patients [46]. Two validation studies (N=22 and 980 patients with SSD) confirmed that ISST is reliable and valid if used to assess ongoing suicidal ideation in patients with SSD [46]. Both ISST and CDSS can be used to provide information necessary in the case management of patients with SSD and suicidal risk [47].

Based on its properties, CDSS is considered a first-line instrument to determine the severity of depressive symptoms in patients with SSD, and a review that compared 6 different instruments targeting the same symptoms formulated this recommendation [44]. A study that explored the diagnosis of major depressive episodes in 84 patients with schizophrenia found that CDSS was superior to the Beck Depression Inventory (BDI), HAMD, and PANSS-D when evaluating the Receiver Operating Characteristics (ROC) curves [48].

However, the possibility that PPD symptoms may be, in fact, the continuation of depressive symptoms with onset in the acute psychotic phase, can not be completely excluded [7]. On the other hand, if PPD is detected after a period of psychotic symptoms remission, then it may be considered part of a new episode of schizophrenia [7].

PPD may be confounded with negative symptoms of SSD, as previously mentioned. The discussion about primary and secondary negative symptoms is a very complex topic, that clearly exceeds the objective of this paper. As a general definition, primary negative symptoms are intrinsic to schizophrenia, a specific clinical dimension, while secondary negative symptoms derive from the presence of positive symptoms, depression, antipsychotics’ pharmacodynamical properties, substance use disorders (SUDs), and social withdrawal [49-51]. After the remission of psychotic symptoms, the depressive symptoms were still present, although their rate decreased from 60% during the acute psychotic episode, to 40% after 5 years follow-up [52].

In conclusion, a correct diagnosis of PPD should include a clinical and psychometric evaluation of psychotic and depressive symptoms, a thoroughly-conducted screening for comorbidities (organic, toxic, or psychiatric) [53-55], an analysis of the risk factors for the persistence of depressive symptoms [56,57], a clear collection of personal medical history (in order to establish the temporal succession of psychotic and depressive manifestations), and an accurate pharmacological anamnesis.

THERAPEUTIC INTERVENTIONS FOR PPD

Adapting the type and dosage of antipsychotic agents in patients with SSD was signaled by different authors as a method to decrease the risk of PPD [2]. Re-evaluation of the main drugs administered during the acute phase of psychosis or the prescription of adjuvant antidepressants or ECT has also been suggested as a case management strategy in PPD [2]. Psychotherapeutic, social, and institutional support are useful options for patients with PPD [2].

A review (n=20 articles) exploring the results of available pharmacological and psychosocial treatments of PPD after the first episode of psychosis did not find support for one intervention in favor of another [58]. Online psychotherapy and treatment with ω-3 polyunsaturated fatty acids (PUFA) have been associated with some favorable results [58].

Olanzapine (5-15 mg/day) was compared to risperidone (4-8 mg/day) in the treatment of PPD (according to the DSM IV criteria) in patients with schizophrenia (N=76), and a clinically significant decrease in MADRS scores (-4 points vs. baseline) was reported after 8 weeks of treatment with either antipsychotic [59]. This study used a randomized, double-blind, parallel-group design. The comparative analysis of the two interventions did not detect any significant MADRS differences at the end-point [59]. A high response rate (≥20% reduction in MADRS scores) was observed during antipsychotic treatment [59]. In order to control for possible confounders of PPD, patients with akinetic symptoms were excluded from this trial [59]. The same team reported on another randomized, placebo-controlled trial, with 24 patients diagnosed with schizophrenia or schizoaffective disorder and PPD or negative symptoms, who continued their six-month adjunctive imipramine to fluphenazine decanoate/ benztropine mesylate treatment or were tapered to placebo + fluphenazine decanoate/benztropine during one year [60]. More patients receiving a placebo relapsed into PPD, at a statistically significant level; also, patients who received placebo experienced relapses into psychoses [60]. Yet another trial conducted by the same team showed that double-blind, controlled discontinuation of imipramine after stabilization (N=14 participants with schizophrenia undergoing treatment with fluphenazine + benztropine) led to relapse into PPD in all patients with placebo vs. only two out of eight in the antidepressant-receiving group (significant difference, p=0.009) [61].

A controlled trial investigated the effects of imipramine hydrochloride for PPD for six weeks, in a double-blind manner [62]. All patients (N=33) were diagnosed with schizophrenia or schizoaffective disorder and received a stable dosage of fluphenazine decanoate and one week-trial with benztropine mesylate was initiated to rule out akinesia; all participants were either non-psychotic or only residually psychotic at baseline [62]. The PPD diagnosis was based on current major or minor depression for at least four weeks, and a HAMD score ≥12 for at least three consecutive weeks [62]. The depressive symptoms (according to HAMD and SADS, Schedule for Affective Disorders and Schizophrenia scores) were controlled better with imipramine vs. placebo and their global clinical status (according to the CGI scores) also improved more consistently in patients receiving the active drug [62]. The psychotic symptoms and tolerability profile did not change significantly between groups [62]. The use of adjunctive imipramine to fluphenazine was further explored by the same team, in a larger and more heterogenous study group [63]. The positive effects of the combined treatment were still detected in the total sample, but the significance of the results was lower [63]. These differences were explained in a post-hoc analysis by the higher level of psychotic symptoms severity, and by “more refractoriness of depression” due to failed previous trials of antidepressants [63].

In a continuation trial, four out of five patients previously stabilized on imipramine + fluphenazine decanoate + benztropine for PPD relapsed into depression six months after the tapering of the antidepressant [64]. The control group, consisting of four patients who did not discontinue imipramine, did not present depressive relapses [64]. The same research team reported on ten PPD patients with good responses to imipramine who relapsed six months after discontinuation of the antidepressant, that was added to fluphenazine decanoate and benztropine [65].

A 24-week double-blind trial compared haloperidol (mean dose 17.5 mg/day) and thiothixene (mean dose 31.8 mg/day) in 46 outpatients with schizophrenia, from their efficacy and safety properties [66]. One of the outcomes was the incidence of treatment-emergent depression, assessed by the Hamilton Depression Rating Scale (HAMD) and Zung Self-Rating Depression Scale (ZSRS) [66]. Haloperidol was superior to thiothixene on the “cognitive disturbance” HAMD factor [66]. Clinically significant symptoms were reported in five patients treated with haloperidol and three receiving thiothixene [66]. The impact on the psychotic symptoms was also more important for haloperidol, according to the Brief Psychiatric Rating Scale (BPRS) scores [66].

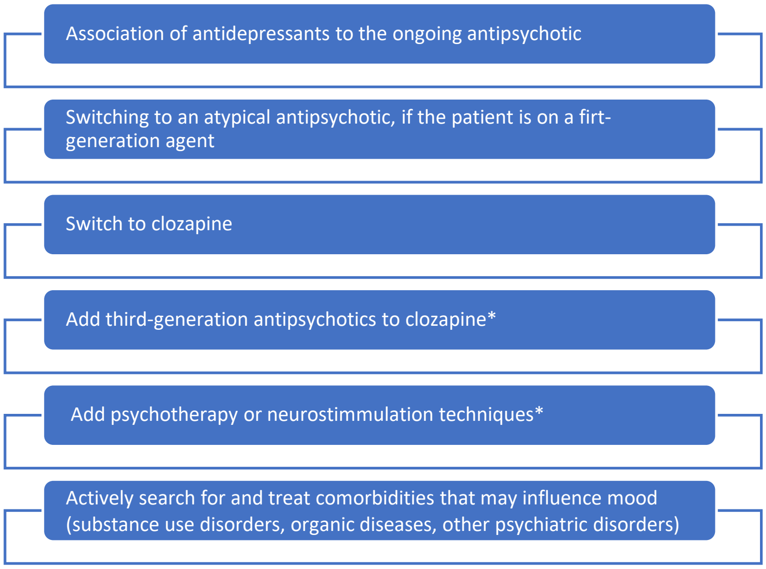
In a trial that compared the antidepressant effects of fluphenazine decanoate (mean dose 32.8 mg fortnightly) and flupenthixol decanoate (mean dose 36.9 fortnightly) administered two-weekly in a group of 48 out- and inpatients with schizophrenia during 15 weeks [67]. No significant differences could be found between groups regarding the number and severity of mood impairments and depression

[67]. Nineteen patients developed depression, and the addition of clomipramine was necessary for five participants, with a mean duration of four weeks, and an average dose of 75 mg/day [67]. The onset of depressive symptoms was reported between days 14 and 70 for outpatients and between days 7 and 77 for inpatients [67]. The onset of depression was unrelated to the antipsychotic dose [67]. The instruments used to assess depression in this trial were HAMD, von Zeersen's self-evaluation scale, and AMP-system [67].

According to a review of 7 studies focused on the use of antidepressants in patients with SSD, tricyclic antidepressants administered in combination with first-generation antipsychotics are a safe choice after the acute psychotic phase is controlled [68]. The risk of exacerbating residual psychotic symptoms is considered minimal by the authors of that review [68]. Still, these antidepressants were ineffective against anergy, considered a core symptom of PPD [68]. This is a controversial conclusion because "anergy" can be easily confounded with several negative signs of schizophrenia (such as avolition, apathy, or even anhedonia) [13,49,50,52,69,70]. The incidence of negative symptoms in patients with SSD is reported to be high, with more than 57% presenting with at least one such symptom, and 41% with at least two negative symptoms [69]. Other authors report a prevalence of negative symptoms that may reach 90% for at least one such manifestation, and up to 60% for at least one depressive symptom in FEP [70]. There is a risk of anticholinergic adverse events because of the pharmacokinetic interactions between the two classes of pharmacological agents [68].

Clozapine is considered a good therapeutic intervention in SSD associating mood disorders [71]. Risperidone was superior to haloperidol in decreasing anxiety and depression scores (at 8 mg/day and 10 mg/day, respectively), and the same atypical antipsychotic was more effective than haloperidol and levomepromazine on the Psychotic Anxiety Scale (at 8.6 mg/day, 9.2 mg/day, and 125 mg/day, respectively) [71]. Another review (n=33 studies focused on treatments for SSD with mood symptoms) concluded that combined treatments are as effective as antipsychotics used in monotherapy for acute psychotic exacerbations with depressive manifestations, although "some evidence" for superiority was detected in the case of antipsychotics [72]. For patients developing a major depressive syndrome after remission of acute psychosis, there has been found evidence to support the administration of antidepressants, as add-ons to antipsychotics [72]. The results regarding therapeutic response to antidepressants in cases of subsyndromal depression were mixed [72].

Figure 2: Potential therapeutic interventions for post-psychotic depression



Association of antidepressants to the ongoing antipsychotic
Switching to an atypical antipsychotic, if the patient is on a firt-generation agent
Switch to clozapine
Add third-generation antipsychotics to clozapine*
Add psychotherapy or neurostimmulation techniques*
Actively search for and treat comorbidities that may influence mood (substance use disorders, organic diseases, other psychiatric disorders)

**= extrapolated recommendations from studies with other populations than patients with post-psychotic depression; not yet enough evidence to support their use*

Newer antidepressants have been launched in clinical use, but their efficacy profile in patients with PPD still remains unexplored [73-77]. Also, older antidepressants may be of interest for this topic, if added to atypical antipsychotics, because, as previously reported, the rate of residual depressive symptoms in this population is quite high [52,78]. Other interventions, besides antidepressants and atypical antipsychotics, are waiting to be investigated in clinical trials for depressive symptoms or major depressive episodes associated with SSD [79-81]. Adding third-generation antipsychotics to clozapine, in cases of ultra-resistance to treatment SSD cases, would also have to be considered a viable option for controlling depressive and negative symptoms [82,83]. Exploring organic, toxic, and psychiatric risk factors for treatment resistance is important when analyzing the most adequate treatment plan for patients with depression, PPD included [84-85].

CONCLUSIONS

The controversy surrounding the diagnosis of PPD is still under scrutiny, because (1) SSDs associate a high rate of suicide, even after the introduction of new generation antipsychotics, (2) there is a significant impact of depression on the quality of life and functional recovery in SSD patients, and (3) the case management of PPD may differ from the interventions recommended in patients with schizoaffective disorder, major depression with psychotic features, adverse events of different drugs with CNS depressogenic properties, and other conditions that may present themselves with depressive symptoms. The data about efficient interventions for PPD derives from older studies, therefore new trials exploring new generations of antidepressants are needed for this population. Based on the reviewed data, there are elements referring to risk factors, clinical characteristics, epidemiology, and even treatment for PPD, but they need to be validated by prospective, good-quality trials.

Abstract: *We aimed to evaluate the efficacy of adsorption therapy as an extracorporeal blood purification technique in critically ill patients with Coronavirus disease 2019 (COVID-19). A retrospective analysis was performed on 17 adult patients with severe COVID-19, who underwent adsorption therapy using an HA330 cartridge, at Ankara City Hospital. Each adsorption therapy was administered for three consecutive days, and each therapy session lasted three hours. Several parameters, including cytokine levels, blood count, biochemistry panel, clinical status, and mortality rate were assessed before and after each therapy session. The results obtained from this study revealed that adsorption therapy reduced IL-6 levels and improved oxygenation in the short term. However, heart rate, mean arterial pressure and SOFA score did not demonstrate significant changes. Notably, the dose of norepinephrine increased after the third session. Regrettably, only 4 out of 17 patients (23.5%) survived. Consequently, adsorption therapy appears to be effective in reducing IL-6 levels in severe COVID-19 patients. Nonetheless, further investigation is warranted to evaluate its impact on clinical outcomes.*

Keywords: *Adsorption therapy; coronavirus disease 2019; cytokine storm; extracorporeal blood purification*

INTRODUCTION

COVID-19 infects the airway epithelium, leading to widespread damage, severe inflammation, and pneumonia with a cytopathic effect. A cytokine storm, capillary leak syndrome, lung injury, and Acute Respiratory Distress Syndrome (ARDS) are all brought on by the local and circulating cytokines that are produced at this time [1-4]. In patients with severe COVID-19, several inflammatory mediators are involved, and the cytokine storm has a deleterious impact on the disease's progression [5].

Additionally, COVID-19 exhibits immunological dysfunction. Techniques for extracorporeal blood purification have previously been utilized as supportive therapy to manage immunological dysregulation in the treatment of sepsis [6]. Despite the use of a variety of treatments, critically ill COVID-19 patients have consistently significant mortality rates. As a result, the use of cytokine filters as a therapy option for these individuals is now being given further thought.

Patients with COVID-19 have considerably higher levels of proinflammatory cytokines and chemokines like tumor necrosis factor-α, interleukin 1 and 6, granulocyte-colony stimulating factor, monocyte chemoattractant protein-1, interferon gamma-induced protein-10, and macrophage inflammatory proteins 1-α [7]. In individuals with severe COVID-19, these proinflammatory cytokines and chemokines lead to a cytokine storm. The extracorporeal removal of these cytokines from COVID-19 patients' blood circulation using an adsorption therapy is hypothesized to minimize hyperinflammation and calm the cytokine storm. Extracorporeal blood purification systems do not only remove pathogenic toxins and proinflammatory mediators; they also remove regulating cytokines. As a result, their process is non-selective. These regulatory cytokines are also advantageous because they restrain the immune system from overreacting to inflammation [8]. Therefore, while the application of extracorporeal blood purification procedures may have short-term advantages, its possible adverse effects on long-term outcomes have not yet been thoroughly assessed and understood.

An adsorption therapy, which is an extracorporeal blood purification technique can be used as a cytokine filter in severe COVID-19 patients. For this aim, an extracorporeal filter which is a cartridge with a sorbent inside is used for blood purification by combining convection and diffusion for solute removal [9]. Additionally, through ionic attraction, hydrophobic interactions, hydrogen bonds, and van der Waals interactions, the sorbent in the cartridge comes into direct contact with blood to adsorb solutes [10,11]. The sorbent in the cartridge also targets TNF, IL-1, IL-6, IL-10, IL-18, and other cytokines [11]. Thus, cytokines and solutes in the bloodstream bind to the sorbent material. Therefore, adsorption therapy can also be used for patients with autoimmune diseases, chronic uremic symptoms, intoxications, and inflammatory conditions with cytokine storms such as sepsis and pancreatitis [9,12].

For adsorption therapy in COVID-19 patients, the Jafron HA330 cartridge can be used [13]. The neutro-macroporous resin-adsorbing beads in the HA330 cartridge are constructed of the styrene-divinylbenzene copolymer. The resin beads' average diameter ranges from 0.60 to 1.18 mm and is 0.8 mm. The resin's pore sizes range from 500 D to 60 kD, whereas the HA330 cartridge removes molecular weights from 10 to 60 kDa (kiloDalton; Dalton [9,12]. Multiple pore sizes of the sorbent material allow the removal of several molecules with different molecular weights such as free hemoglobin, cytokines, complements, drugs, uremic toxins, and protein-bound or hydrophobic substances. The recommended treatment duration with an HA330 cartridge is 2-2.5 hours, while the sorbent material can be saturated if it is used for a longer period which causes a decrease in clearance efficiency [9,12].

In this study, we wanted to assess the efficacy of adsorption therapy in patients with severe COVID-19. To understand the effects of adsorption therapy using HA330 cartridges in severe COVID-19 patients in the intensive care unit (ICU), we evaluated the changes in the clinical status of patients, cytokine levels, complete blood count, and biochemistry panel before and after the administration of the therapy

MATERIALS AND METHODS

A retrospective analysis was performed on 14 male (82.3%) and 3 female (17.6%) adult severe COVID-19 patients who received adsorption therapy (HA330 cartridge, Jafron) in the ICU at Ankara City Hospital between April 2020 and October 2021 (Table 1). Before and after adsorption therapy with HA330, the patients' laboratory results and clinical outcomes were assessed. Ankara City Hospital (E2-21-983) granted permission for this study with the approval of the local ethics committee.

Table 1: Characteristics of severe COVID-19 patients treated with HA330 adsorption cartridge

Characteristics of COVID-19 patients	
Demographics	
Age (years) (median, IQR)	53.5 (45-62.5)
Gender, male (n, %) female (n, %)	14 (82.3) 3 (17.6%)
Treatment	
Methylprednisolone 40 mg (n, %)	17 (100)
IVIG (n, %)	1 (5.8)
Anakinra (n, %)	9 (52.9)
Tocilizumab (n, %)	1 (5.8)
Outcomes	
Length of ICU stay (days) (median, IQR)	22 (34)
Mechanical ventilator duration (days) (median, IQR)	20 (30)
Survived (n, %)	4 (23.5)
Died (n, %)	13 (76.5)

1 IQR: interquartile range. IVIG: intravenous immunoglobulin. ICU: intensive care unit. Anakinra: An interleukin-1 receptor antagonist. Tocilizumab: A monoclonal antibody against the IL-6 receptor. In this study, 14 male (82.3%) and 3 female (17.6%) adult patients with severe COVID-19 were treated with adsorption therapy (HA330 cartridge, Jafron©) in the ICU. The median age of the patients was 53.5 (IQR: 45-62.5). All 17 patients received a ten-day course of iv methylprednisolone 40 mg once daily. Of the patients, nine were treated with anakinra, one with tocilizumab, and one received IVIG treatment without tocilizumab or anakinra. Four patients died after the first adsorption therapy session, and another four died after the second. Nine patients completed three sessions of adsorption therapy, but five of them died due to sepsis and ARDS-related complications in the ICU. Overall, 4 out of 17 critically ill COVID-19 patients survived after adsorption therapy with an HA330 cartridge (23.5%).

Respiratory distress with peripheral capillary oxygen saturation (SpO_2) 93% in room air, dyspnea with a respiratory rate of at least 30 breaths per minute, a ratio of the partial pressure of arterial oxygen to the fraction of inspired oxygen (PaO_2/FiO_2) less than 300 mmHg, and more than 50% infiltration of the lung fields are all considered to be severe COVID-19 in adult patients [14]. Moreover, cytokine release syndrome was defined as having one or more of C-reactive protein >100 (or >50 mg/L but doubled in the past 48 hours), lymphocyte count <0.6 × 109/L, serum interleukin-6 (IL-6) level higher than 3 times of the upper normal limit, ferritin >300 ug/L with doubling within 24 hours, ferritin >600 ug/L at presentation and LDH >250 U/L, and elevated D-dimer (>1 mcg/mL) [15]. These 17 patients had confirmed COVID-19 diagnoses based on real-time reverse transcription polymerase chain reaction (RT-PCR) test results and ground glass appearance with pneumonia on thorax computed tomography before admission to the ICU. They also had previously defined severe COVID-19 disease and cytokine release syndrome features. The exclusion criteria for this study included being under the age of 18, having severe heart failure with a left ventricular ejection fraction of less than 35%, having coagulation issues, and being pregnant.

All 17 patients received methylprednisolone 40 mg iv once daily for ten days. 9 patients were treated with anakinra, whereas 1 patient was treated with tocilizumab. 1 patient received immunoglobulin (IVIG) treatment without tocilizumab or anakinra.

Adsorption therapy was initially planned for 3 hours daily with an HA330 cartridge for 3 consecutive days. However, adsorption therapy could be applied to 17 patients once, 13 patients twice, and 9 patients three times. Thus, creatinine, glomerular filtration rate, urea, albumin, alanine transaminase (ALT), aspartate transferase (AST), total bilirubin, lactate dehydrogenase (LDH), troponin, fibrinogen, D-dimer, lactate, ferritin, erythrocyte sedimentation rate, C-reactive protein (CRP), procalcitonin, interleukin-6 (IL-6), hemoglobin, neutrophil/lymphocyte ratio (NLR), number of leukocytes, neutrophils, lymphocytes, and platelets were noted before and after adsorption therapy sessions. Additionally, the patients' vital signs, requirements for vasopressor medications, partial pressure of oxygen to fraction of inspired oxygen (PaO_2/FiO_2), and Sequential Organ Failure Assessment (SOFA) scores were recorded from their medical records before and after adsorption therapy sessions.

Statistical evaluation was performed using the Statistical Packages for the Social Sciences (v17.0, SPSS 24 Inc., Chicago, IL) software. Categorical data were presented as numbers and percentages, while quantitative data were presented as mean standard deviation or median and interquartile range (IQR), as appropriate. The differences between the two groups were evaluated with the Mann-Whitney U test and the Wilcoxon test. The statistical significance level was accepted as p<0.05.

RESULTS

Adsorption therapy with a Jafron HA330 cartridge was applied once to 17 patients, twice to 13 patients, and three times to 9 patients. The median age of the patients was 53.5 (IQR: 45-62.5). The median ICU length of stay was 22 (IQR:34) days. The median mechanical ventilator duration was 20 days (IQR:30). The median APACHE II score was 18 (IQR:10). The median length of stay in the ICU before the initiation of adsorption therapy was 4 days (IQR:2-6) (Table 1).

Table 2: Clinical status of patients before and after 1st, 2nd and 3rd sessions of adsorption therapy with HA330 cartridge

Clinical parameters	Before adsorption therapy (IQR)	After 1st session (IQR)	*P**	After 2nd session (IQR)	*P**	After 3rd session (IQR)	*P**
PaO_2/FiO_2 (mmHg) (n=12)	0.59 (0.46-0.92)	0.69 (0.47-0.95)	*0.12*	0.54 (0.46-0.69)	*0.44*	0.62 (0.51-0.71)	*1.0*
HR (bpm/min) (n=13)	87.0 (66.5-100.0)	80.0 (69.5-102.5)	*0.72*	77.0 (67.5-120.0)	*0.86*	90.0 (72.8-113.8)	*0.74*
MAP (mmHg) (n=14)	80.0 (73.8-102.5)	80.0 (68.8-97.5)	*0.44*	75.0 (65.0-92.5)	*0.23*	71.5 (61.2-96.0)	*0.53*
Dose of NE (µg/kg/min) (n=9)	0.12 (0.04-0.43)	0.15 (0.03-0.67)	*0.46*	0.04 (0.12-0.17)	*0.89*	0.25 (0.07-0.19)	*0.11*

*[2] Numerical data were given as a median and interquartile range (IQR). PaO_2/FiO_2: partial pressure of arterial oxygen/the fraction of inspired oxygen. HR: Heart rate. MAP: Mean arterial pressure. NE: norepinephrine. SOFA: Sequential Organ Failure Assessment. *Wilcoxon test was used.*

The first, second, and third sessions of adsorption therapy using the HA330 cartridge are shown in Table 2 along with the patients' clinical status before and after each session. For each clinical parameter, including PaO_2/FiO_2, heart rate (HR), mean arterial pressure (MAP), norepinephrine dose (NE), and Sequential Organ Failure Assessment (SOFA) score, the median and interquartile range (IQR) are shown in the table. According to these findings, the first adsorption therapy session led to a statistically significant increase in PaO_2/FiO_2 levels (p=0.03), whereas the second and third sessions did not. None of the three sessions of adsorption therapy resulted in statistically significant changes in heart rate, mean arterial pressure, or SOFA score.

The dose of NE showed a statistically significant increase after the third session of adsorption therapy (p<0.11). Overall, these data imply that the use of an HA330 cartridge in adsorption therapy may improve oxygenation in patients with severe COVID-19, but larger sample sizes and additional research are required to confirm these results.

Table 3 shows the variations in cytokine levels, complete blood counts, and biochemistry panels in severely ill COVID-19 patients receiving first, second, and third adsorption therapy sessions using HA330 cartridges. A statistically significant decrease in IL-6 levels was observed after the first, second, and third adsorption therapy sessions (361, 86.5, 28, 20.3, p<0.03, p<0.03, p<0.007, respectively). There was a statistically significant increase in leukocyte count after the first adsorption therapy compared to the leukocyte count before adsorption therapy (12.2 to 14.6, p=0.02). However, the leukocyte count decreased from 14.6 to 12.9 after the 2nd session and increased to 13.5 after the 3rd therapy session, neither of which was statistically significant (p=0.42, p=0.12, respectively). When compared to the neutrophil count prior to the first adsorption therapy (10.9 to 13.6, p=0.03), there was a statistically significant rise in neutrophil count.

However, the neutrophil count climbed to 12.1 after the third therapy session but declined to 11.6 after the second (p=0.46 p=0.19). Neither change was statistically significant (Table 3).

Table 3: Statistical analysis of laboratory parameters of severe COVID-19 patients before and after first, second, and third sessions of adsorption therapy with HA330 cartridge

Laboratory parameters	Before adsorption therapy (n=17) (IQR)	After 1st session (n=17) (IQR)	*P**	After 2nd session (n=13) (IQR)	*P**	After 3rd session (n=9) (IQR)	*P**

*[3] Numerical data are given as a median and interquartile range (IQR). NLR: neutrophil-lymphocyte ratio, GFR: glomerular filtration rate, ALT: Alanine transaminase, AST: Aspartate transferase LDH: lactate dehydrogenase, INR: international normalized ratio, ESR: erythrocyte sedimentation rate, CRP: C-reactive protein, IL-6: interleukin-6. (-): data could not be retrieved. There was a statistically significant decrease in IL-6 levels after the first, second, and third adsorption therapy sessions (361, 86.5, 28, 20.3, p <0.03, p<0.03, p<0.007, respectively). *Wilcoxon test was used*

There was a statistically significant increase in the neutrophil-lymphocyte ratio (NLR) after the first adsorption therapy compared to the NLR before adsorption therapy (20.2 to 28.8, p=0.03). Although the NLR dropped from 28.8 to 24.3 after the second session and then further to 23.4 after the third (p=0.20 and p=0.80, respectively), neither of these decreases was statistically significant. When compared to the albumin level before the initial adsorption therapy, there was a statistically significant drop in albumin (29.0 to 28.0, p=0.04). However, albumin increased from 28.0 to 30.0 after the second session and reduced to 28.0 after the third (p=0.20 and p=0.49, respectively), neither of which was statistically significant.

No statistically significant changes were observed in creatinine, glomerular filtration rate, urea, alanine transaminase (ALT), aspartate transferase (AST), total bilirubin, lactate dehydrogenase (LDH), troponin, fibrinogen, D-dimer, lactate, ferritin, erythrocyte sedimentation rate, CRP, procalcitonin, hemoglobin, glucose, lymphocyte, or platelet count after the first, second, and third sessions of adsorption therapy with HA330 cartridges. Four patients died after the first, and another four patients died after the second adsorption therapy session. Nine patients completed three sessions of adsorption therapy. However, five of these nine patients died due to sepsis and ARDS-related complications in the ICU. Only 4 out of 17 critically ill COVID-19 patients survived after adsorption therapy with an HA330 cartridge (23.5%).

DISCUSSION

There are a limited number of publications in the English medical literature related to the use of extracorporeal blood purification techniques with the United States Food and Drug Administration (FDA) approved filters such as oXiris filter (Baxter, Deerfield, IL), CytoSorb filter (CytoSorbents, Monmouth Junction, NJ), Seraph 100 Microbind blood affinity filter (ExThera Medical, Martinez, CA) and the Spectra Optia Apheresis System with the Depuro D2000 Adsorption Cartridge (Terumo BCT, Lakewood, CO) for the treatment of COVID-19 patients [8]. According to Padala et al., using an oXiris filter improved clinical outcomes in two out of three patients and reduced levels of interleukin-6, erythrocyte sedimentation rate, and CRP [16]. According to Zhang et al., CRP, IL-6, IL-8, IL-10, APACHE II, and Sequential Organ Failure Assessment (SOFA) scores all significantly decreased after oXiris filter treatment, while IL-4, IL-8, and procalcitonin showed a nonstatistically significant downward trend. Unfortunately, two of five patients passed away despite treatment [2]. Ugurov et al. reported using oXiris in ten patients with COVID-19. Two of the ten patients passed away related to complications of ARDS. According to Ugurov et al., the number of white blood cells and thrombocytes increased to the normal range whereas IL-6, CRP, and fibrinogen levels decreased [17]. According to Villa et al., treatment with oXiris resulted in a significant drop in IL-6 levels as well as improvements in hemodynamic stability, multiorgan dysfunction, and oxygenation index in 37 patients [18].

Case studies of COVID-19 patients who received treatment with a CytoSorb filter were described by Rizvi et al., Melegari et al., and Berlot et al. [1, 19, 20]. All three patients survived with an improvement in CRP, IL-6, and oxygenation. Rieder et al. treated 4 patients under venovenous extracorporeal membrane oxygenation (vv-ECMO) support with cytokine adsorption with CytoSorb filter, which decreased IL-6 in COVID-19 patients [21]. According to Alharthy et al., continuous renal replacement therapy (CRRT) sessions using a CytoSorb cartridge were administered to 50 patients. Thirty-five patients who survived after CytoSorb therapy had decreased ferritin, lactate dehydrogenase, CRP, IL-6, and D-dimer levels [15].

According to Olson et al., the Seraph-100 filter was utilized in two COVID-19 patients, and as a result, post-treatment vasopressor dose, IL-6, and CRP levels decreased [22]. The use of a Seraph-100 filter on a patient with COVID-19 significantly decreased D-dimer level, according to Pape et al. [23]. Four hemodialysis patients with severe COVID-19 were treated using a Seraph-100 haemoperfusion device, according to Sandoval et al. Despite findings from other research, Sandoval et al. failed to find any appreciable drop in IL-6, D-dimer, or ferritin levels following the treatment [24]. According to Schmidt et al., 78 COVID-19 patients who received treatment with a Seraph-100 microbind affinity blood filter were evaluated. According to Schmidt et al, patients who received Seraph-100 treatment within 60 hours of ICU admission had a reduced mortality rate [25].

Reverse Takotsubo cardiomyopathy associated with COVID-19 was treated with therapeutic plasma exchange utilizing a Spectra Optia apheresis system outfitted with a Depuro D2000 adsorption cartridge, according to Faqihi et al. Following treatment, both lactate levels and left ventricular function returned to normal [26].

Koc et al. published a review of hemadsorption therapy in severe COVID-19 patients [13]. 86 patients with severe COVID-19 were included in 16 trials that were examined by Koc et al. CytoSorb®, oXiris®, Biosky filter, SeaStar® CLR filter, HA280, HA330 Jafron, and resin-directed hemadsorption cartridges were used in hemoperfusion therapy. According to Koc et al., the mortality rate, mean intubation time, and length of stay in the ICU and hospital were, respectively, 29%, 14.93 days, 17.21 days, and 31.7 days. Following hemoperfusion sessions, the mean levels of CRP and interleukin-6 reduced (131.7 to 66.0 and 527.5 to 334.7, respectively). According to Koc et al., hemoperfusion and cytokine adsorption reduced cytokine levels, CPR, and IL-6 relative to pre-therapy, decreased mortality to 29%, and improved clinical conditions. However, these outcomes lacked statistical significance. Hemadsorption therapy was described by Koc et al. as an alternate salvage therapy for COVID-19 patients who were critically unwell. Moradi et. al reported a 73-year-old male patient was treated with hemoperfusion (HA230 cartridge, Jafron) due to a cytokine storm for 4.5 hours [27]. Moradi et al. claimed that the symptoms and need for oxygen support were alleviated during hemoperfusion treatment.

Theoretically, blocking the formation of proinflammatory cytokines can reduce hyperinflammation. The clinical outcome of severely ill COVID-19 patients can be improved by reducing hyperinflammation. Thus, anti-interleukin-6R monoclonal antibodies and corticosteroids were recommended to reduce the inflammatory response. However, IL-6 promotes neutrophil-mediated viral clearance by initiating a preliminary response against viral infections [7]. Moreover, Dienz et al. reported that IL-6 or IL-6 receptor-deficient mice could not resist Influenza A infection, which caused pulmonary damage leading to death [28]. Despite its theoretical benefit, Clark et al. reported that hemoperfusion was an experimental treatment because of its limited evidence of efficacy [29]. However, Kang et al. reported that in patients with severe COVID-19 and non-acute kidney injury, continuous renal replacement therapy using an oXiris filter might not be able to successfully reduce cytokine release syndrome [30].

Hemadsorption therapy has several additional drawbacks. Arrhythmia, coagulation issues, thrombocytopenia, and bleeding were listed as the most typical short-term hemoperfusion consequences in patients with COVID-19 by Darban et al. [31]. However, the majority of the difficulties emerged on the second and third days following hemoperfusion, not during hemoperfusion itself.

A highly biocompatible sorbent covered with a surface that inhibits platelet adherence and clotting activation is necessary for hemoperfusion. The various sorbent types utilized determine how hemoperfusion removes substances, with the effective surface area being a key factor. The sorbent material within the hemoperfusion cartridge can both absorb and lead to the loss of antibiotics and nutrients from the bloodstream [9, 10, 32].

The Jafron HA330 cartridge was the only available single-use hemoperfusion cartridge at Ankara City Hospital. Thus, we performed adsorption therapy on severe COVID-19 patients in the ICU with single-use Jafron HA330 cartridges. We used adsorption therapy as a salvage therapy when the patients did not respond to other treatment options such as antibiotics, corticosteroids, hydroxychloroquine, immunoglobulin, convalescent plasma, tocilizumab or anakinra [33].

There is still no single laboratory parameter with a cut-off value identified to initiate adsorption therapy. Moreover, the duration of therapy and the parameters to monitor the patient’s response to the treatment are still under investigation [6]. Unfortunately, there is no universally accepted standardized adsorption therapy protocol. We preferentially used adsorption therapy to treat severely ill COVID-19 patients with low procalcitonin but high CRP and IL-6 levels.

Except for a decline in IL-6, we were unable to find a statistically significant link between the quantity of adsorption therapy sessions and laboratory values. The majority of the research previously cited showed that adsorption treatment reduced IL-6 levels. However, anakinra and tocilizumab might be responsible for the IL-6 decline in COVID-19 patients [34].

Moreover, our study has certain drawbacks. First of all, the sample size was quite small. Secondly, during the pandemic, we mostly served severe COVID-19 patients in our intensive care unit, which restricts the applicability of our findings to other patient populations. Finally, because a control group was not included in our investigation, additional variables, such as medication modifications and illness progression, might have an impact on the observed changes in laboratory values. Hopefully, our study contributes to the growing body of research on the use of adsorption therapy in COVID-19 patients despite these limitations.

CONCLUSION

After examining this study's data, it can be concluded that in patients with severe COVID-19, the use of an HA330 cartridge during adsorption therapy was connected to a statistically significant drop in IL-6 levels after the first, second, and third therapy sessions. Except for a rise in the leukocyte and neutrophil counts following the first session, there were no statistically significant associations between the quantity of adsorption therapy sessions and other laboratory findings.

To draw a definitive conclusion about the effect of adsorption therapy with HA330 cartridges on COVID-19 patients, further studies with larger and more diverse patient populations are needed. These studies should also consider other potential confounding factors, such as the administration of other treatments and underlying medical conditions. Nevertheless, the findings of this study point to the possibility that adsorption therapy could be a potential supplementary treatment option for individuals with severe COVID-19.

Abstract: *The article shows the development of the method of psychological evaluation called "Evaluation of Negative Mental Reactions and States of Combatants". In the study participated 1300 male servicemen (29.84% from junior lieutenant to colonel and servicemen under contract and demobilized, and 70.16% from private to senior warrant officer). The age of participants varied from 20 to 55 years. The system of evaluation developed consisted of 16 instruments that could help to determine the presence of negative psychological symptoms of servicemen related to their participation in hostilities. The results indicated that the evaluation method developed is a tool that allows determining the presence of negative psychological symptoms related to participation in combat. Likewise, it is a useful and fast method to assess the effectiveness of short-term psychological recovery programs. Unlike existing methods of diagnosing negative mental reactions and states of an individual, which arose after their participation in hostilities, the developed psychodiagnostic toolkit could consider the physical and mental fatigue of the respondents, their deterioration, and other cognitive dysfunctions*.

Keywords: *combat activity, psychological rehabilitation, psychological recovery, post-traumatic stress disorder, evaluation system*

INTRODUCTION

Long participation in hostilities depleted the psychological adaptation resources of servicemen, sharply posing the question concerning the need for psychological recovery [1,2]. This issue was complicated and comprehensive; it related both to the definition of rotation of servicemen and to the determination of the duration and development of effective programs of psychological recovery for all participants of hostilities [3] as well as to the determination of indications for medical and psychological rehabilitation of the servicemen, whose mental health and ability to readaptation was lost [4]. The aim of psychological recovery was to restore the physical and mental resources of servicemen to prolong their ability to perform tasks under the conditions of combat stress factors action [5].

Nowadays, the psychological decompression measures were directed not only to ensuring the adequacy of switching from military service to peaceful life [6], including traditional stress relief and help in civilian life realization, taking into account the acquired military experience, accepting this experience to reduce the probability of post-traumatic stress disorders (PTSD) formation [7,8], but also for the psychological restoration of mental health of servicemen who participated in hostilities to relieve the accumulated stress prolonging the possibility of adequate functioning of servicemen under combat conditions when it was impossible to realize the massive rotations to keep their resistance – psychological stability, ability to resist negative influence from the side of combat stress factors [2]. To the institutions of psychological recovery were sent the servicemen with expressed signs of maladjustment [9], acute stressful reactions [7], significant exhaustion, devastation, and fatigue [10], and servicemen, who had difficulties in adaptation [11] while getting back in line after injuries and concussion and after their stay in hospitals.

Institutions that implemented psychological recovery programs were located in the third echelon of defense in safe places in order to form in the minds of servicemen the idea of the need to return to the performance of combat missions, and military duty, which was a way of posing the direction of recovery – the restoration of combat capacity.

Realization of activities of psychological rehabilitation and implementation of existing psychological programs of decompression on the basis of their personal professional experience and world experience of rehabilitation of servicemen was imposed on the military psychologists of the Armed Forces and the National Guard of Ukraine, as well as on the volunteer psychologists from NGOs who had appropriate training and experience. Usually, the implementation of psychological recovery programs was a combination of procedures of medical treatment orientation with the use of appropriate material and technical bases and the involvement of appropriate specialists.

Even though the system of implementation of the psychological restoration of combat servicemen was well-established and proved its effectiveness in practice, there arose a question on the development of effective psychodiagnostic tools of the mental state control of servicemen before and after a complex of actions by the program of psychological rehabilitation for individual servicemen and correction of the recovery program if required. There were distinguished the following requirements for the psychodiagnostic method:

1) convenient while conducting both individual and group psycho-diagnosis of servicemen, typical for a survey with a large number of people (100-200 people), capable of taking into account the physical and mental fatigue of the respondents, deterioration of their attention, and other cognitive dysfunctions related to stressful experience;

2) suitable for the diagnosis of negative mental reactions and conditions that occur after participation in hostilities;

3) reliable for re-diagnosis due to a minor period of time, excluding the ability to remember accurately their past answers;

4) able to clearly demonstrate changes in psychological state that occurred during their participation in the psychological recovery program;

5) convenient for summarizing data and receiving the psychologist's feedback on the effectiveness of the introduction of new actions into the programs of psychological recovery;

6) useful for obtaining information related to the effectiveness of individual consulting, providing a psychologist with a reflection on his/her professional activity. With existing pressure on psychologists, there occurred a need for supervision and their rotation in institutions that dealt with psychological recovery.

The objective of the study was the development of a psychological evaluation system of the consequences of participation in combat activities for military personnel participating in hostilities. Unlike the existing systems to diagnose the psychological consequences of combat participation, it is intended to develop a set of psychodiagnostic tools that assess the physical and mental fatigue of combatants, their deterioration, and other cognitive dysfunctions. And also, that it is capable of clearly showing the psychological changes achieved by participation in psychological recovery programs.

MATERIALS AND METHODS

Participants and Procedure

The study was conducted in 2022. The study included 1300 servicemen who underwent a psychological recovery program after taking part in a long combat mission. The tested group consisted of officers – 29.84% (from junior lieutenant to the colonel) and servicemen under the contract and mobilized – 70.16% (from private to senior warrant officer). The age of the study participants varied from 20 to 55 years.

While developing the method "Evaluation of negative mental reactions and states of combatants", there were combined the simplest procedures of conditions evaluation which were typical for the method such as "Profile of mood states" (POMS) [12,13], "Self-esteem of psychophysiological state" (Kokun) [14], "Measurement of states" used to express evaluation of emotional states of sportsmen [15]. Also, there was conducted analysis of negative mental reactions and states that often occurred in servicemen while their participation in hostilities, including those who described the ability to perform tasks and the ability to interact with others in the performance of command work [1,16]. Thus, the list of negative mental reactions and states (experience) was quite wide and contained 16 points: irritability; anxiety; aggressiveness;

anger; inattention; self-doubt; devastation; apathy; concern; sense of guilt; sense of powerlessness; lack of concentration; unwillingness to communicate; lack of trust in comrades in the service; lack of trust in commanders; inability to perform the assigned tasks. It was assumed that the use of factor analysis would give the possibility to group these points into the scale.

It was necessary to point out that the simplicity of the instructions and of the testing procedure itself was an important circumstance for effective diagnostic work with servicemen who had been experiencing the influence of combat stress factors for a long time and who had difficulty in the redistribution of attention.

However, a number of points (16) of the evaluation of negative mental states but the evaluation scale itself (from 0 to 10 points) was quite large (exceeding the amount of short-term memory 7±2 elements), which complicated their memorization and accuracy reproduction during re-testing.

The determination of psychometric indicators of the method “Evaluation of negative mental reactions and states of combatants” and its testing was carried out during the participation in a psychological recovery program by servicemen. 1300 servicemen participated at this stage.

The servicemen filled out the form of the method at the beginning of the psychological recovery program and after it. The results obtained in accordance with the method “Evaluation of negative mental reactions and states of combatants” were compared with the results of methods that were conducted with servicemen to control their condition before and after their participation in the psychological recovery program. Before participating in a psychological recovery program, servicemen were surveyed with the following methods: “Maladjustment” (Prykhodko, Matsegora, Kolesnichenko, and Baida) [17], “Mississippi Scale for Combat-Related PTSD” (Keane, Caddell, and Taylor) [18], “Diagnostics of psychological safety of an individual” (Prykhodko, 2012) [19], “Evaluation of traumatism of combat experience of servicemen” (Kolesnichenko) [20]. After participating in the psychological recovery program, servicemen were surveyed in accordance with the following psychodiagnostic methods – “Resistance to psychological traumatism of combat experience” (Kolesnichenko) [21].

All procedures in the study conformed to the ethical standards of the 1964 Helsinki Declaration and its later amendments. All participants consent for their data to be used in this research.

Instruments and Measures

To determine the constructive validity of the method "Evaluation of negative mental reactions and states of combatants" there were used methods which were standardized on the Ukrainian selection.

Method "Maladjustment" (Prykhodko, Matsegora, Kolesnichenko, and Baida) [17] was an express version of the method "Adaptability" (Maklakov) [22] which had a long tradition of use in the Armed Forces of Ukraine. The "Adaptability" method was concluded by military psychologist A.H. Maklakov [22] to determine the adaptation potential of servicemen based on the individual scales of the method "Minnesota Multiphasic Personality Inventory" (McKinley, Hathaway) [23]. The developer reported satisfaction with the psychometric characteristics of the formed methodology [22]. Since the beginning of hostilities in eastern Ukraine among military psychologists of Ukraine, there was spread a modification of the methodology proposed by Maklakov "Adaptability 200", carried out by Chermianin and Kondratiev [24]. Unlike the previous method, it was supplemented with a number of issues that allowed us to distinguish "military and professional orientation", "tendency to deviant behaviors", and "suicidal risk" and to calculate "the level of resistance to combat stress". This method included 200 questions; thus, there was a need to form a simpler and more reliable toolkit, which was the basis for the development of an express version of the method. The developed method "Maladjustment" (Prykhodko, Matsegora, Kolesnichenko, and Baida) [17] was aimed at the identification of specific violations of adaptation potential which could have a big influence on the ability to adequately perform the tasks. Thus, the method had 4 scales, each with 10 questions – "Violation of behavioral regulation", "Probability of committing suicidal attempts", "Violation of moral normativity" and "Loss of communicative potential". There was highlighted the calculation of the general indicator of "Maladjustment". This calculation was simple and convenient and could be carried out under field conditions without any additional tools. Although working with the method involved the presence of trust in psychologists, the method had a scale of sincerity. The developers provided data about the satisfactory psychometric indicators of the method.

The study used the "Mississippi Scale for Combat-Related PTSD" (Keane, Caddell, and Taylor), which was restored for the Ukrainian selection [18]. Nowadays, it was one of the most common methods used to measure the signs of PTSD. The scale included 35 statements, each of which can be estimated on a five-point scale. The total indicator which was made up in accordance with this method gave the possibility to estimate the degree of influence of the traumatic experience transferred by an individual.

"Diagnosis of Psychological Safety of an Individual" (Prykhodko), which was developed on the basis of the concept of psychological safety of an individual of specialists of extreme activities [19]. According to this concept, psychological safety was not only a lack of danger but also an opportunity for development and self-realization. Psychological safety had a level structure. Each level in the method met a scale with a similar name. The first level was moral and communicative, it meant that knowledge and use of the rules of communication and norms of morality made interaction with the social environment controlled and predictable, formed the ability to escape potentially conflict situations, and involved external resources to overcome problematic situations. The motivational and volitional levels suggested that the developed goal setting, intensity in goal setting, and flexibility in their corrections could ensure the self-realization of an individual in difficult conditions of life. It was assumed that the ability to flexible restructuring of relations with the environment gave the possibility to be leading in these relationships, to control them. The valuable and semantic level was considered as an ability to conscious attitude to one's own life, awareness of one's own influence on the world, and responsibility for its changes. The developer believed that this conscious attitude gave the possibility for an individual to tolerate life difficulties and sufferings that arose in the process of self-realization. Moreover, due to the developer, the hierarchy of the semantic sphere gave the possibility to depreciate the experience in frustration as unimportant and to consolidate efforts to achieve important aims. The level of internal comfort was the factor that provided a change in the direction of activity. Thus, the evaluation of life as safe, and the condition as comfortable contributed to the decision to continue normal regulation. The decisions related to the changes were made in case of non-compliance of the environment with the needs and capabilities of an individual. There was highlighted the calculation of the general indicator of psychological safety of an individual, its height indicated the ability to set new goals of self-realization. When the indicators were reduced the thing was in a supportive reproduction of usual goals of life or in the arrest of development, and further impossibility of self-realization. The developed method had satisfactory psychometric indicators. The National Guard of Ukraine had been using this method for more than 10 years.

The method of "Evaluation of traumatism of combat experience of servicemen" [20] was based on the American method "Combat Exposure Scale" [25]. In the process of its development, there were considered the traumatic events and their intensity which were typical for military actions in Ukraine with the beginning of the Russian invasion in 2014. Unlike the "Combat Exposure Scale" method, the method of "Evaluating of traumatic experience of servicemen" (Kolesnichenko) had been developed; it included a list of phenomena that gave the possibility to reduce the trauma of combat stress factors influence. The method had 5 scales that met 3 groups of combat stress factors and 2 factors that described internal and external resources used to counteract stress factors. In the process of standardizing the method, there was used the procedure of regressive analysis which gave the possibility to determine the contribution of each scale to acute stress disorder which occurred due to the action of combat stress factors. It was reported that the method had satisfactory psychometric characteristics.

The method "Resistance to psychological traumatism of combat experience" (Kolesnichenko) [21] was developed on the basis of the author's concept of combat psychological traumatism of servicemen [1]. The method reflected the given in this concept three levels (stages) of realization of resistance to the action of combat stress factors, which 1) were related to the preparation for activity under the conditions of combat stress factors and under the existing expectations concerning the stress factors' activity and their ability to overcome them, 2) had the direct ability to overcome stressful influence and used adequate situational copings, and 3) had the ability to accept and realize the acquired experience under the stressful conditions. There was provided the calculations of general resistance to combat psychological traumatism. It was reported that this indicator had a reverse correlation with the "Mississippi Scale for Combat-Related PTSD" (Keane, Caddell, and Taylor) [18], r = -0.60, p≤0.01. Moreover, the method of the scale of the second order – "helplessness", "conscious attitude to professional training", "ability to acquire experience", "cognitive dysfunction", and "attitude to military duties". The method had satisfactory psychometric indicators.

Data Analysis

To represent the data, there was used the main descriptive statistics (arithmetic mean M and standard deviation SD). To distinguish the correlational rate between the variables there was used the correlation analysis. To determine the internal coherence of the method "Evaluation of negative mental reactions and states of combatants" there were used calculations based on Cronbach's alpha. To determine the specific negative mental reactions and states which were experienced by servicemen due to their participation in hostilities there was used regression analysis. To determine the structure of the method "Evaluation of negative mental reactions and states of combatants" there was used factor analysis with the help of the method "Principal components". Mathematical data was processed with the help of SPSS 17.0.

RESULTS

We have developed the following form of psychodiagnostic method "Assessment of negative mental reactions and states in combatants" (Table 1). The instructions are as follows:

"Please assess your psychological state at the moment on a scale from 0 - slightly expressed, 10 - strongly expressed". The internal consistency of the method was evaluated using the α-Cronbach indicator, which was 0.944 having the selection of 1300 people for 16 indicators.

Table 1: Form of the methodology "Evaluation of negative mental reactions and states of combatants"

Mental reactions and states	Evaluation of reactions and states										
Irritability	0	1	2	3	4	5	6	7	8	9	10
Anxiety	0	1	2	3	4	5	6	7	8	9	10
Aggressiveness	0	1	2	3	4	5	6	7	8	9	10
Anger	0	1	2	3	4	5	6	7	8	9	10
Inattention	0	1	2	3	4	5	6	7	8	9	10
Self -doubt	0	1	2	3	4	5	6	7	8	9	10
Devastation	0	1	2	3	4	5	6	7	8	9	10
Apathy	0	1	2	3	4	5	6	7	8	9	10
Concern	0	1	2	3	4	5	6	7	8	9	10
Sense of guilt	0	1	2	3	4	5	6	7	8	9	10
Sense of powerlessness	0	1	2	3	4	5	6	7	8	9	10
Lack of concentration	0	1	2	3	4	5	6	7	8	9	10
Unwillingness to communicate	0	1	2	3	4	5	6	7	8	9	10
Lack of trust in comrades in the service	0	1	2	3	4	5	6	7	8	9	10
Lack of trust in commanders	0	1	2	3	4	5	6	7	8	9	10
Inability to perform the assigned tasks	0	1	2	3	4	5	6	7	8	9	10

Despite the fact that the developed method included negative mental reactions and states for evaluation of PTSD, and maladjustment, and testified both negative experiences and inability to manage their behavior, its purposefulness and inability to maintain interaction and consistency in teamwork, factor analysis which was conducted in accordance with "Principal Components" presented the presence of only one factor that included all 16 variables with different factors of factor evaluation: "irritability" (0.743), "anxiety" (0.796), "aggressiveness" (0.692), "anger" (0.722), "inattention" (0.744), "self-doubt" (0.744), "devastation" (0.808), "apathy" (0.733), "concern" (0.808), "sense of guilt" (0,793), "lack of concentration " (0.801), "unwillingness to communicate" (0.714), "lack of trust in comrades in the service" (0.640), "lack of trust in commanders" (0.675), "inability to perform the assigned tasks" (0.746).

Taking into account the received data, the method included the calculations of general indicators. Experience using the method had shown that the most convenient indicator was the calculation of the average arithmetic value for all 16 indicators. Thus, the general indicator had a range from 0 to 10 points, which was convenient to perceive general results by the method and did not require memorization of additional information for manual data processing.

It was necessary to point out that the selection of a single-factor structure of the method was a certain confirmation of less regularity of negative mental reactions and states, a reflection of greater integration of mental processes while operating under stressful conditions.

The determination of the validity of the method was conducted in two stages. In the first stage, to determine the constructive validity, the data of the method "Evaluation of negative mental reactions and states of combatants" was compared with the data of methods which gave the possibility to diagnose the peculiarities of negative mental reactions and states of servicemen, proving that they were related to their participation in hostilities. First of all, the talk was about the method "Maladjustment" which gave the possibility to evaluate the violation of "behavioral regulation", "the probability of committing suicidal attempts", "violation of moral normativity" and "loss of communicative potential" by servicemen [17], and "Mississippi Scale for Combat-Related PPSD" (Keane, Caddell, and Taylor) [18], which gave the possibility to diagnose PTSD symptoms of those who had participated in hostilities and left the battlefield [24]. Moreover, there was used the method of "Evaluation of traumatic experience of servicemen" (Kolesnichenko) [20] and "Resistance to psychological traumatism" (Kolesnichenko) [21], which in this study gave the possibility to connect the experience of negative mental reactions and states with the experience of participation in hostilities, as well as with their peculiarities and preparation for them.

Correlational relations with the method of "Diagnosis of psychological safety" (Prykhodko) [19] indicated the depth of violation of personality structures, which ensured its safety and ability to develop, which was an important factor for making a prognosis for the restoration of an individual in the process of psychological decompression and rehabilitation. The results of correlational analysis, which were obtained at this stage of validity determination were given in Table 2. Considering that the selection of the study at this stage included 1300 people, then all the correlational indicators given reached the level of statistical significance and did not require additional indicators.

Dense correlation relations of the method "Evaluation of negative mental reactions and states of combatants" and methods such as "Maladjustment" (Prykhodko et al.) [17] and "Mississippi Scale for Combat-Related PTSD" (Keane, Caddell, and Taylor) [18] pointed out that according to the data provided by the developed method, it was really possible to consider negative experience, which was connected with adaptation disorders and PTSD symptoms. The data provided by the method "Evaluation of traumatic experience of servicemen" [20] proved that negative experience was mostly related to the force of negative effects than to the existing external support.

However, the formed personality structure (according to the method "Diagnosis of Psychological Safety" [19] including the process of professional and professional-psychological training, due to the method "Evaluation of traumatism of combat experience of servicemen" [20] was able to restrain the development of negative states, providing adequate functioning of an individual under combat conditions. But at this stage, it was impossible to monitor the accumulated influence of traumatic events on the development of negative mental states while exceeding the recommended time for rotation (more than 6 months).

The second stage of determination of the method's validity was developed to determine its ability to be a tool for tracking the dynamics of changes during psychological recovery. The methods which were used at the first stage had satisfactory indicators of reliability, and, therefore, could be insensitive to the changes which occurred during the week (this was a usual term of the program of psychological recovery of servicemen). The method of "evaluation of negative mental reactions and states of combatants" was developed specifically for evaluating the control of negative states' changes before and after participation in the psychological recovery program, including the possibility to evaluate its effectiveness. Considering such purpose, the data obtained by the method "evaluation of negative mental reactions and states of combatants" before and after the participation in the recovery program was compared to the data obtained by Lüsher's color test including the indicator of anxiety. This indicator pointed out the availability of frustrated needs and inadequacy of compensation and, unlike other indicators by this projective method, could be confused with indicators by other methods. The indicator of anxiety in accordance with Lüsher's color test was used as an integrated state evaluation since the main determinants of mental states were the ratio: firstly, conscious and unconscious needs, desires, and aspirations of an individual; secondly, the capabilities of an individual (obvious abilities and hidden potentials); thirdly, environmental conditions (objective influence and subjective perception of the current situation) [25].

40 servicemen participated at this stage of the study. Thus, the general indicator by the method "evaluation of negative mental reactions and states of combatants" correlated with anxiety before the beginning of the decompression program at a moderate level – $r = 0.41$, $p \leq 0.01$; after the decompression program the data was – $r = 0.47$, $p \leq 0.01$. These data proved that the developed method was sensitive to the changes in states and could be used to evaluate the dynamics of states during the programs of psychological recovery which were developed for short-term (up to a week).

It was figured out that the general indicator (see Table 2) had a slightly higher density than individual indicators by the method "evaluation of negative mental reactions and states of combatants" with general indicators of maladjustment, PTSD, psychological safety of an individual, traumatism of combat experience, and resistance to psychological traumatism. It was another piece of evidence that the method would be more reliable if it was used as a single scale.

Then there was used the procedure of regression analysis to determine specific negative mental reactions and states experienced in these psychological categories; thus, there were formed relevant regression equations:

Maladjustment = 3.804 + 0.216*Irritability + 0.307* Aggressiveness + 0.259*Self-doubt + 0.249*Devastation + 0,245*Concern + 0.386*Reluctance to communicate + 0.229* Lack of trust in comrades in the service + 0.350*Lack of trust in commanders +0.264* Inability to perform the assigned tasks + 0,529.

Post-traumatic stress disorder = 54.66 + 1,070*Irritability + 0.719*Aggressiveness + 0.572*Inattention + 0.557* Devastation + 1.230*Apativity + 0.794*Concern + 0.613* Unwillingness to communicate + 0.602*Lack of trust in commanders +0.941* Inability to perform the assigned tasks +0.506.

Table 2: The indicators of correlative relations between the scales of method "Evaluation of negative mental reactions and states of combatants" and the scales of other psychodiagnostics methods which were used to estimate its validity (in points).

Indicators	"Estimation of negative mental reactions and states of combatants"																
	Irritability	Anxiety	Aggressiveness	Anger	Inattention	Self-doubt	Devastation	Apathy	Concern	Sense of guilt	Sense of powerlessness	Lack of concentration	Unwillingness to communicate	Lack of trust in comrades in the service	Lack of trust in commanders	Inability to perform the assigned tasks	General indicators due to the method

Psychological safety of an individual = 5.325 – 0.072*Irritability – 0.064*Devastation – 0,077*Sense of guilt – 0,095*Sense of powerlessness – 0.071* Reluctance to communicate + 0.775.

Traumatism of combat experience = -17.672 + 0.426*Anxiety + 0.393*Apathy + 0.502*Inability to perform the assigned tasks + 0.789.

Resistance to combat psychological traumatization = 167.165 – 2.514*Anxiety + 2.869*Anger – 1.621*Apathy – 1,510* Lack of trust in comrades in the service – 4.812*Inability to perform the assigned tasks + 0.599.

The procedure of regression analysis had to give the possibility to reduce the dimension of measurements for each state, but as it could be seen, the error of evaluation in the concluded regression equations was quite high, especially in the process of predicting traumatism of combat experience (e = 0.789) and psychological safety of an individual (e = 0.775) that made it inappropriate to use them for calculations. However, the information obtained through regression analysis gave the possibility to better understand the experience of servicemen who had different negative symptoms due to their participation in hostilities.

Moreover, a long-last period of testing and a large selection of the study had shown that the calculations made with the help of regression analysis by individual scales were less accurate than the normalized general indicator by the method (that indicated one more time the importance of using the method as a single scale). It was the regulation for different negative symptoms that prevailed in determining the ways of processing data by the method.

Thus, the obtained data showed that if the general indicator by the method "Evaluation of negative mental reactions and states of combatants" exceeded 3.5 points, then 65.45% of servicemen-participants of the psychological recovery program were likely to be symptoms of maladjustment by the same method. If the average points according to the developed method were 5 or more, then more than 85% of servicemen with this indicator were diagnosed with expressed symptoms of maladjustment.

The comparison of the general indicator by the method "evaluation of negative mental reactions and states of combatants" with the method "Mississippi Scale for Combat-Related PTSD" (Keane, Caddell, and Taylor) [18] showed that while exceeding 3.5 points according to the scale of the developed method more than 90% of servicemen with this indicator had expressed PTSD symptoms. When the average quantity of points was 5.5% – 100% of servicemen who participated in psychological recovery activities had an indicator that exceeded the norm by the "Mississippi Scale for Combat-Related PTSD" (Caddell and Taylor) [18].

The comparison with the data provided by the method "Resistance to psychological traumatism of combat experience" showed that with general points 3 or more in accordance with the method "Evaluation of negative mental reactions and conditions of combatants" 75.59% of servicemen with such quantity of points were diagnosed with an unsatisfactory indicator of resistance (from 0 to 143 points).

If the general indicator was exceeded in accordance with the method "Evaluation of negative mental reactions and states of combatants" the score of 5 points meant that low resistance to combat psychological traumatism was diagnosed in almost 86% of servicemen who participated in psychological recovery activities.

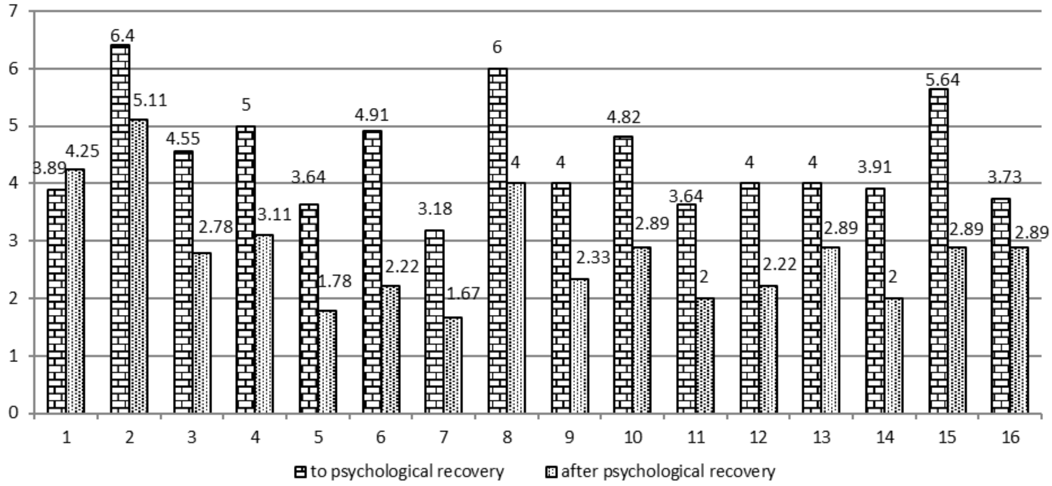
The comparison with the express method "Psychological Safety of an Individual" (Prykhodko) [19] and "Evaluation of traumatism of combat experience of servicemen" (Kolesnichenko) [20] pointed out that if the points were less than 3 by the general scale of the method "Evaluation of negative mental reactions and states of combatants" 89% of servicemen retained satisfactory indicators of psychological safety of an individual, and 85.41% were diagnosed with low trauma of combat experience.

More reliable for these two methods was a forecast concerning psychological well-being than negative symptoms.

Thus, the given data showed that for the general indicator by the method "Evaluation of negative mental reactions and states of combatants" it was normal to have a high probability of negative symptoms' absence (PTSD, maladjustment, instability to combat psychological traumatization, and psychological safety of an individual) and it also showed that high ability to recover was possible when an indicator was less than 3 points.

It was necessary to point out that the results obtained with the help of the method, both individual and group ones, were convenient to present in the form of column histograms. As an example, there was proposed the histogram of the dynamics of negative mental reactions and conditions of servicemen with signs of maladjustment (in particular, violation of behavioral regulation) in the process of one of the decompression courses (Figure 1).

Figure 1: Dynamics of negative mental reactions and conditions while participating in psychological recovery in a group of servicemen with violation of behavioral regulation (in points)



Notes: 1 – inability to perform the assigned tasks; 2 – lack of trust in commanders; 3 – lack of trust in comrades in the service; 4 – unwillingness to communicate; 5 – lack of focus; 6 – sense of impotence; 7 – sense of guilt; 8 – concern; 9 – apathy; 10 – devastation; 11 – self-doubt; 12 – inattention; 13 – anger; 14 – aggressiveness; 15 – anxiety; 16 – irritability

DISCUSSION

According to Ukrainian [14] and foreign specialists [26,27], early diagnosis of negative mental reactions and states [28], post-stress states, and determination of a group of increased psychological attention among personnel gave the possibility to identify servicemen with low personal adaptive potential and high probability of early and severe manifestations of combat psychological traumas [29] and its consequences [30]; also gave the possibility to create individual tactics and methods of prevention and restoration of each surveyed serviceman. To solve the problem of diagnosis of negative mental reactions and states of servicemen, it was suggested to use the following psychodiagnostic tools: "The Hospital Anxiety and Depression Scale (HADS) ", "Brief Scale of Anxiety, Depression, and PTSD", "The Montgomery-Asberd Depression Rating Scale (MADRS)” [31], "Beck Depression Inventory (BDI)" [32], "Primary Screening for Post-Traumatic Stress Disorder (PTSD)", "Mississippi Scale for Combat-Related PTSD" (Keane, Caddell, and Taylor) [18], "Impact of Event Scale–Revised (IES-R)" [33], "Patient Health Questionnaire (PHQ)-9" [34], "Clinical-administered PTSD Scale" [35], "Neurotization and Psychopathization (LNP) questionnaire" [14] and others. As an additional diagnostic tool, at the request of a psychologist, there was used the method "The Suicidal Behaviors Questionnaire-Revised (SBQ-R)" [36] to diagnose the suicidal inclinations of servicemen. However, this psychological study could have been placed under the conditions of medical and psychological rehabilitation which lasted not less than two weeks, but it was quite difficult to realize this tool under the conditions of psychological recovery, which lasted not more than one week.

Traditionally, in clinical practice, there had been used for a long time the projective method such as Lusher's color test, in particular after psychotherapy and training activities for self-regulation and restoration of adaptive capacity, the selection of colors could be compared with the so-called autogenic norm by Wallnöfer [37].

World tendencies in psychological studies showed that the diagnosis of mood, mental reactions, and conditions was relevant not only for the needs of the clinic but also in the workplace. The study of workers’ moods and states was an important component of the psychological well-being (health) of workers. These studies were extremely large-scale and attracted thousands of working people as participants [38]. Such interest in the problem of studying the state of a working person, as an indicator of his/her psychological well-being, was quite clear since the psychological state was a holistic, systematic, integral formation of human psychological activity. The psychological state of an individual could be internally and externally observed, it acted as a regulatory function of adaptation to the external situation and environment [16]. According to the definition by Kirilenko, the psychological state was the formation of psychological activity, which reflected the moment of stability and specificity of psychological processes’ duration, as a form of response, and reflected the attitude of an individual toward his/her own psychological phenomena at a certain point in time under certain conditions [39]. Varii pointed out that the psychological state was a temporary functional level of the psyche, which reflected the interaction of the influence of the internal environment of the body or external factors and determined the orientation of psychological processes' duration at a certain moment and manifestation of psychological properties of an individual [40]. The author defined the following areas in the studies of mental states: 1) mental states were an integral characteristic of the psyche at a particular moment; 2) psychological states were the background on the bases of which operated the psychological activity and orientation of the psychological activity of an individual; 3) it was a systemic reaction of the human psyche to changes of the conditions.

Volzhentseva highlighted that the leading functions of mental states were the regulation and integration into functional units, which were formed in the hierarchy of a single, holistic set of psychological processes and properties [25]. According to the author, the adaptive function of the psychological state was to establish the correspondence between the current needs and capabilities of an individual, considering the external conditions, features of activity, and behavior.

It was likely that the integration and integrity of psychological states became the basis for reducing the dimensions of the methods which were intended for their research. Thus, in foreign scientific sources, it was reported that to determine the moods and conditions, which were important indicators of short-term effects of intervention, was also used in clinical practice, "The Profile of Mood States (POMS)" [12,41]. This scale was developed by American experts, it had the form of a self-report and included 65 elements that related to 7 different scales: depression, anxiety, fatigue, energy, irritability, tension, and confusion.

The answer scale was divided into 5 categories from "not at all" to "completely yes". However, German psychologists in the re-standardization of POMS [12,13] created a shortened version of the method that included only 35 points which belonged to the scale "Depression/anxiety", "Fatigue", "Energy" and "Irritability" [38]. Another study was intended to reduce the dimension of POMS [41]. For this purpose, the POMS scale [12,13] with the help of regression analysis correlated with "The Eight State Questionnaire" (8SQ) [42], which was formed to measure anxiety, stress, depression, regression, fatigue, guilt, extraversion, and excitement. Researchers found that the excessiveness of measurement between these two methods mainly referred to negative emotional states.

CONCLUSIONS

Thus, the developed method "evaluation of negative mental reactions and states of combatants" was a tool that gave the possibility to determine the presence of negative psychological symptoms of servicemen related to their participation in hostilities and was a convenient tool for estimation of the dynamics of the state under the conditions of short-term programs of psychological recovery without the use of complex evaluation procedures and calculation of data.

Abstract: *Currently, the educational process must integrate new tools, to keep pace with technological progress. Our paper aims to investigate the extent to which the preferences of medical students for the autonomous use of multimedia resources in the learning process are correlated with their opinions towards the Internet and the intensity of using it in their daily activities. Methods: We investigated 395 medical students from 4 medical universities in Romania, 75.9% females, and 88.8% in the 1st and 2nd years of study. Students were asked to express on Likert-scales their agreement with a list of statements about Internet services, as well as whether they like learning using multimedia tools and how intensively they use Internet services. Results: The students agree to a medium to large extent with the favorable statements about Internet services but are also aware of the negative influences that indiscriminate use of such technology can have. The intensity of Internet usage is high, although not exaggerated. With small exceptions, the students who enjoy using multimedia resources during the learning process have also favorable opinions about Internet services, and use them constantly, mainly for information and instant messaging on social networks*.

Keywords: *multimedia-based learning; blended learning; Internet services; social networks; medical students*

INTRODUCTION

Currently, digital technology has become increasingly used in everyday activities, and its intensive use in most fields of activity has attracted changes in the structure of society, and even in the psychology of individuals, who gradually change their conceptions about life, work, and education, about the ideal way of spending leisure time and about the features of an optimal work climate. In this general context, it is obvious that the educational process must integrate new tools, in an attempt to keep pace with technological progress. The protagonists of this process, students as well as teachers, are people with a fundamentally different lifestyle than 20 years ago, with different expectations and conceptions.

The most obvious changes are noticed in the case of the current generation of students. This is the so-called "Generation Z" (children born after 1997), also known as iGen, post-millennial, or digitally native. These are children who have been exposed to technology from the beginning of their lives, so using computers and gadgets has become second nature to them, as have the activities online and on social networks. Consequently, these children prefer to study independently, at their own pace, using visual or kinaesthetic didactic tools, which give them immediate feedback. It is important for them to respect the right to privacy and personal space; they are pragmatic, entrepreneurial, and generally reluctant to take risks (because they faced periods of economic recession in childhood); although they generally enjoy interaction with the teacher, Generation Z children have fewer social skills associated with face-to-face communication and the art of conversation, compensated instead by intense online activity [1].

There are currently relatively few studies in the literature concerning Generation Z issues, which usually focus on describing its characteristics [2,3], effective strategies for recruitment in the public sector [4], and individuals' attitudes towards work [5], but without focusing on the specific problems of medical students of this generation, with their own needs, preferences and learning styles.

Obviously, the learning style of Generation Z students has features that differentiate it from the learning styles preferred by other generations of students. The most preferred method is active learning (through discussion and involvement in practical projects), based on sensory stimuli (visual - images, graphics, auditory and kinetic). Knowledge is achieved through observation, practice, and quick and targeted access to the necessary information through the use of technology and online resources: e.g. YouTube for video tutorials, Facebook (for chatting with classmates and sharing projects and teaching materials), or Google (for documenting and searching for scientific references). Students prefer self-study, at their own pace, with a flexible schedule and teaching materials that intensively use multimedia resources: explanatory or demonstrative video sequences, PowerPoint presentations with audio support, simulations, collaborative projects, discussion forums, online questionnaires, and case studies in the classical environment (seminar room or practical works). In this context, the portrait of the ideal teacher has also changed significantly: firstly, he must be a good communicator, close and friendly, transparent, enthusiastic, passionate and competent in his field, able to propose realistic goals and to provide immediate and constructive feedback on their achievement, willing to provide professional and emotional support to his students, both academically and individually, to prepare them for their future careers.

In this context, the concept of blended education, based on the intensive integration of digital resources into the teaching process, is becoming increasingly popular among teaching tools.

Such education programs are usually developed in mixed regimes, online and onsite, combining as much as possible in an optimal manner the advantages of both methods. Blended courses are a current trend that provides a new and effective instructional experience to the students they address, and have several major advantages:

- Flexibility in the teaching schedule, which simplifies students' access to the course, regardless of their physical location and allows them to organize their time and pace of learning according to their own needs and availability;

- More effective teaching: Most scientific studies show that blended teaching is more effective than traditional courses, but also than full online courses. A 2009 report from the United States examined 51 studies comparing online and traditional methods and concluded that students enrolled in blended learning programs score on average better on exams than those enrolled in full-onsite programs [6]; on the other hand, blended teaching programs also perform better than fully online ones as well [7], as they still give to the students the opportunity to interact effectively with the teacher when needed.

- Clearer organization of content: It is the natural result of a well-designed blended course, which must provide students with clear and detailed indications of using the proposed resources, activities, and tests, helping them to concentrate better and proposing an optimal pace of learning, in the same way that the teacher guides students onsite in going through the exposed materials;

- Stimulation of active learning, which emphasizes the student's autonomy in effective learning communities;

- Lower costs: Reducing the number of onsite meetings frees up the teaching spaces of the institution and reduces some utility expenses. The teachers and the students will gain lower transport costs and time savings, although logistics expenses can be slightly increased (it is necessary to purchase adequate personal computers and involves additional costs for electricity consumption and telephone subscription).

Our paper aims to investigate the extent to which the preferences of students at medical faculties for the autonomous use of multimedia resources in the learning process are correlated with their opinions towards the online environment and the Internet and the intensity with which they use such resources in their daily activities, not necessarily related to the learning process.

MATERIALS AND METHODS

We conducted a case study that enrolled 395 medical students from 4 medical universities in Romania. The general features of the sample are shown in Table 1. Students are 3 quarters females (75.9%); most students are in the 1st and 2nd years of study (88.8%), aged between 18-20 years (74.4%), with an average age of 21.78 ± 3,736 years and a range of variation between 18-48 years.

Also, most students come from faculties of Dental Medicine (34.4%) or General Medicine (47.6%), mainly from the "Grigore T. Popa" University of Medicine and Pharmacy in Iasi, Romania (50.9%); 27.1% of the participating students are from University of Medicine and Pharmacy in Craiova, and 20.3% from University of Medicine and Pharmacy "Victor Babeș" in Timisoara.

Students were invited to fill in an online questionnaire in order to express their agreement degree with a list of statements about Internet services (favorable – 7 items and unfavorable – 3 items). In addition, they were asked whether they like learning using multimedia tools and resources and how intensively they use different Internet services (7 items).

The agreement degree with the proposed statements was quantified using a 5-step Likert scale, ranging from 1 – very small agreement to 5 – very large agreement.

Table 1: General features of the study sample

		n	%
Gender	masculine	95	24.1
	feminine	300	75.9
Age group	18-20 years	294	74.4
	21-24 years	78	19.7
	over 25 years	23	5.8
Year of study	1	228	57.7
	2	123	31.1
	3	44	11.1
Specialization	Dentistry	136	34.4
	General medicine	188	47.6
	Dental technique	70	17.7
	Prophylaxis assistance	1	0.3
University	UMPh Iasi	201	50.9
	UMPh Craiova	107	27.1
	UMPh Timișoara	80	20.3
	UMPh Cluj Napoca	7	1.8
Total		395	100.0

The questionnaire was presented and explained individually to each study participant.

Participation in the study was voluntary. Participants were informed about the study and the overall objectives of the research and, at the beginning of the questionnaire, were invited to give their informed consent. The questionnaires were completed anonymously.

The study was approved by the Research Ethics Commission of the "Grigore T. Popa" University of Medicine and Pharmacy, Iasi (decision no. 21/16.11.2020).

Statistical analysis

Data collected from students were recorded and processed in SPSS 29.0 (SPSS Inc., Chicago, IL) for Windows.

The responses to each item were characterized by frequency distributions and contingency tables. The numerical variables were characterized by descriptive statistics (mean, standard deviation, standard error, range of variation, and median). Comparisons between samples were made using the Kruskal-Wallis test for quantitative data, after having previously verified that they comply with the normal distribution law, using the Shapiro-Wilks normality tests. We considered the p-value ≤ 0.05 to be statistically significant (*) and the p-value ≤ 0.01 to be statistically highly significant (**).

RESULTS

The 7 favorable statements about the Internet were as follows:
- Item 1: The main advantage of the Internet is that it provides information fast;
- Item 2: The main advantage of the Internet is that it provides correct information;
- Item 3: Freedom of expression should not be restricted on the Internet;
- Item 4: Most people would not be able to cope if they no longer had access to the Internet;
- Item 5: I can't imagine my life without Internet access;
- Item 6: People who socialize on the Internet are happier than others;
- Item 7: If I didn't socialize on the Internet I would be sadder.

88.6% of students evaluate the Internet as a fast source of information (item 1) but are more reserved about its correctness (only 30.6% of them think that information on the Internet is much or very much correct – item 2).

68.9% of students believe that most people would not be able to cope if they no longer had access to the Internet (item 4) and 60.7% believe that they themselves would not be able to cope if there is no Internet (item 5). 53.9% of students believe that freedom of expression should not be limited to the Internet (item 3).

On the other hand, only a small percentage of students believe that socializing in the virtual environment ensures a comfortable psychological status, making them happier (item 6 – 10.9%, respectively item 7 – 21.5%) – Table 2.

The 3 unfavorable statements about the Internet were as follows:
- Item 8: Internet is addictive;
- Item 9: Parents should limit their children's access to Internet to at most one hour;
- Item 10: People's privacy is at risk due to social media.

A large part of students believe that the Internet can be addictive (item 8 – 76.2%). Although they generally do not consider it necessary for parents to limit their children's access to the Internet (item 9 – only 41.0% agree to a large or very large extent), they still believe that people's privacy is at risk due to social networks (item 10 – 59.5%) – Table 3.

Table 2: Favourable opinions about Internet services – students' responses

Favorable opinions about Internet services	Agreement:									
	1 – to a very small extent		2 – to a small extent		3 – in average measure		4 – to a large extent		5 – to a very large extent	
	n	%	n	%	n	%	n	%	n	%
Item 1	1	0.3	4	1.0	40	10.1	125	31.6	225	57.0
Item 2	8	2.0	49	12.4	217	54.9	93	23.5	28	7.1
Item 3	9	2.3	16	4.1	157	39.7	107	27.1	106	26.8
Item 4	7	1.8	25	6.3	91	23.0	143	36.2	129	32.7
Item 5	21	5.3	35	8.9	99	25.1	115	29.1	125	31.6
Item 6	81	20.5	121	30.6	150	38.0	34	8.6	9	2.3
Item 7	75	19.0	118	29.9	117	29.6	46	11.6	39	9.9

Table 3: Unfavourable opinions about Internet services – students' responses

Unfavorable opinions about Internet services	Agreement:									
	1 – to a very small extent		2 – to a small extent		3 – in average measure		4 – to a large extent		5 – to a very large extent	
	n	%	n	%	n	%	n	%	n	%
Item 8	3	0.8	17	4.3	74	18.7	139	35.2	162	41.0
Item 9	43	10.9	56	14.2	134	33.9	94	23.8	68	17.2
Item 10	10	2.5	44	11.1	106	26.8	118	29.9	117	29.6

The consumer of Internet services profile was outlined through another 7 questions, regarding the way, intensity, and main purposes for which students use Internet services. The recorded responses are shown in Table 4.

Most students (97.5%) say they use the Internet daily, and 70.9% of them use the Internet at least 3 hours a day. Almost 1/3 of students (29.4%) believe that they could not give up the Internet without problems even for a day - which indirectly means acknowledging an addiction to this practice. On the other hand, half of students (47.6%) indicate the one-week period as the maximum limit for opting out of the Internet, which is also a limited time frame. Most students access the Internet using their mobile phones (84.6%).

Although they use online services quite intensively, the main objective of students is not written communication – thus, almost 3 quarters of them (71.6%) say they receive/send between 1 - 10 emails per day, and 9.4% say they do not use e-mail at all. Half of students (52.4%) are active on social networks, having over 100 friends; however, there is also a significant percentage of students (20.8%) who have fewer than 10 friends online. In contrast, 74.2% of students post on social media only a few times a year or a few times a month. Therefore, students use social networks in a relatively moderate regime, mainly for instant communication and less for permanent posts.

Finally, the students were asked whether they liked learning, even autonomously, using multimedia tools and resources (Item 18). The answers to this question are generally favorable: 41.5% of students say they like much or very much to learn using multimedia tools, 38.0% of students agree on average with this statement, and only 20.5% of students show a total or partial disagreement (Table 5).

In order to express more precisely the obtained results, we quantified them as numerical scores, calculated as arithmetic averages of the responses. We calculated 2 scores, one for favorable opinions about Internet services (INTF) and one for unfavorable opinions (INTNF), with a range of variation between 1 – 5, which we interpreted as follows:

- Values between 1.00 – 1.49 = agreement to a very small extent;
- Values between 1.50 – 2.49 = agreement to a small extent;
- Values between 2.50 – 3.49 = agreement in average measure;
- Values between 3.50 – 4.49 = agreement to a large extent;
- Values between 4.50 – 5.00 = agreement to a very large extent.

Using the same procedure, we calculated also a third score, to characterize the intensity in using Internet services (INTS) – with a range of variation between 1 – 4 and interpreted accordingly:

- Values between 1.00 – 1.49 = very low intensity;
- Values between 1.50 – 2.49 = low intensity;
- Values between 2.50 – 3.49 = high intensity;
- Values between 3.50 – 4.00 = very high intensity.

The analysis of these scores reveals that students agree to a medium to large extent with the favorable statements about Internet services (INTF = 3.44 ± 0.590), but also with the unfavorable statements about these services (INTNF = 3.69 ±

0.817), being therefore aware of the negative influences that indiscriminate use of such technology can have. The intensity of Internet usage is high, although not exaggerated (INTS = 2.85 ± 0.350) – Table 6.

Table 4: Intensity and main purposes in using Internet services – students' responses

		n	%
Item 11. On average, I access the Internet:	several times a month	3	0.8
	several times a week	7	1.8
	daily	385	97.5
Item 12. On average, the amount of time I spend on the Internet during a day is:	less than 1 hour	7	1.8
	1 - 3 hours	108	27.3
	3 - 6 hours	145	36.7
	over 6 hours	135	34.2
Item 13. I could quit the Internet without problems for a time frame of:	1 year	25	6.3
	1 month	66	16.7
	1 week	188	47.6
	not even a day	116	29.4
Item 14. Generally, I access the Internet using:	a desktop	13	3.3
	a laptop	47	11.9
	a tablet	1	0.3
	a mobile phone	334	84.6
Item 15. On average, the number of emails I receive/send daily is:	none	37	9.4
	1 to 10	283	71.6
	11 to 30	58	14.7
	31 to 50	12	3.0
	over 50	5	1.3
Item 16. The number of friends (contacts) I have on the most frequently used social network is:	under 10	82	20.8
	between 11 and 50	68	17.2
	between 51 and 100	38	9.6
	between 101 and 500	109	27.6
	over 500	98	24.8
Item 17. On average, the frequency with which I post new information on my social media profile is:	none	35	8.9
	several times a year	152	38.5
	several times a month	141	35.7
	several times a week	55	13.9
	several times a day	12	3.0

Table 5: General opinion about the use of multimedia resources during the learning process – students' responses

General opinion	**Agreement:**									
	1 – to a very small extent		**2 – to a small extent**		**3 – in average measure**		**4 – to a large extent**		**5 – to a very large extent**	
	n	**%**	**n**	**%**	**n**	**%**	**n**	**%**	**n**	**%**
Item 18: I like to learn using multimedia tools and resources	19	4.8	62	15.7	150	38.0	81	20.5	83	21.0

Table 6: Internet services usage scores - descriptive statistics parameters

	n	**Mean (M)**	**Standard deviation (SD)**	**Standard error of the mean (SEM)**	**Min**	**Max**	**Median**
Favourable opinions about Internet usage (INTF)	395	3.44	0.590	0.030	1.57	5.00	3.43
Unfavourable opinions about Internet usage (INTNF)	395	3.69	0.817	0.041	1.00	5.00	3.67
Internet usage intensity (INTS)	395	2.85	0.350	0.018	1.71	3.71	2.86

We compared these scores according to the students' degree of agreement with the usage of multimedia resources during the learning process, to identify the possible links between these two elements. We started with the hypothesis that the students who enjoy using digital technologies for entertainment in leisure time should also enjoy using them professionally, respectively during the learning process.

The obtained results are presented in Table 7 and actually validate this research hypothesis.

Table 7: Internet services usage scores – compared according to the degree of agreement with the use of multimedia resources during the learning process

	Agreement:					**Kruskal-Wallis test**
	1 – to a very small extent	**2 – to a small extent**	**3 – in average measure**	**4 – to a large extent**	**5 – to a very large extent**	
	M ± SD	**M ± SD**	**M ± SD**	**M ± SD**	**M ± SD**	
Favorable opinions about Internet usage (INTF)	3.02 ± 0.705	3.43 ± 0.612	3.32 ± 0.545	3.53 ± 0.522	3.67 ± 0.593	H = 23.634 p < 0.001**
Unfavorable opinions about Internet usage (INTNF)	4.02 ± 0.842	3.68 ± 0.692	3.74 ± 0.807	3.58 ± 0.733	3.63 ± 0.973	H = 5.414 p = 0.247
Internet usage intensity (INTS)	2.75 ± 0.415	2.97 ± 0.325	2.81 ± 0.350	2.88 ± 0.324	2.80 ± 0.358	H = 12.310 p = 0.015*

There are statistically significant differences between the scores of favorable opinions about Internet usage, determined by the degree of agreement with the use of multimedia resources during the learning process. The lowest scores are found in students who agree to a very small extent with the use of multimedia resources (3.02 ± 0.705), and the highest in students who agree to a very large extent with the use of multimedia resources (3.67 ± 0.593), so these 2 elements are in clear correlation.

The situation is different for the scores of unfavorable opinions: the highest score of unfavorable opinions about Internet usage is found in students who strongly disagree with the use of multimedia resources in the learning process (4.02 ± 0.842). As the degree of agreement with the use of multimedia resources increases, the score of unfavorable opinions decreases, but with random fluctuations, so the observed differences are not statistically significant.

The lowest score of Internet usage intensity is also found in students who strongly disagree with the use of multimedia resources in the learning process (2.75 ± 0.415) – therefore they are fundamentally against digital technologies. On the other hand, the highest score of Internet usage intensity (2.97 ± 0.325) is observed in students with little agreement for the use of multimedia resources in the learning process – so they are obviously not against digital technologies but probably prefer to use them exclusively for leisure. Students who agree to a medium or large extent with the use of multimedia resources in the learning process have scores of Internet usage intensity between the 2 categories mentioned above, so they enjoy using digital technologies both professionally and for leisure. The differences between the investigated categories of students are statistically significant.

DISCUSSION

The data from the literature prove that multimedia resources are an effective tool for learning because they are able to stimulate the students' interest [8] and improve their cognitive skills [9], also contributing to the development of supplementary skills – like empathy [10,11] or the academic writing [12]. Such tools are preferred by medical students because they tend to be kinaesthetic learners, who use multiple ways to present a topic for a better understanding [13,14,15] – observations also confirmed by our study.

Medical students are advanced users of smartphones and laptops and easily use such devices during their daily activities and learning [15,16] – a fact also confirmed by our results. The students investigated by us are generally interested in digital technologies and their applicability during the learning process [15].

It is thus natural that our students have generally positive opinions about Internet services, without thinking that they are addicted to them. Moreover, they are even aware of the presence of such a risk, which proves realistic and mature thinking. Most students use the Internet for information, although they are also aware of the risk of not obtaining accurate data – a fact confirmed by other literature data as well [17]. We must admit that the media and entertainment tools familiar to previous generations (TV, radio, written press) have now been joined by new, equally important, or even more important partners – the smart devices, which seem to have become the most convenient ways to access virtual environments.

Almost all students use the Internet daily, from their mobile phones, and most of them for at least 3 hours – which shows a certain degree of dependence on this technology, although it is not recognized as such. The most frequently used Internet services are, according to some authors, WhatsApp (as a fast communication solution) [18,19,20], YouTube, and Blackboard [21].

It is also interesting to note that socializing in cyberspace is not very important for our students and does not replace real socialization. Only half of the students have many friends on social media, but even they don't post very frequently (only a few times a year or a few times a month, which is a moderate pace). Moreover, almost 60% of students believe that people's privacy is at risk due to social networks – a result that is questionable, because not the social networks pose a danger, but the people using them inappropriately – an aspect that seems to have been omitted by students. Literature data also confirms that the students, particularly the medical students, are not very well informed about the ethical issues regarding the use of social media resources [21].

There is an obvious and positive association between the degree of agreement expressed by students towards the use of multimedia resources during the learning process and their favorable opinions towards the use of Internet services. This means that the general openness to modern technologies is reflected by integrating them into personal life, but also professionally. On the other hand, unfavorable opinions towards the use of Internet services are associated sometimes with the general avoidance of modern technologies. We also identified a separate category of students who, although they do not like to use multimedia resources in the learning process, are instead very active on the Internet; they are especially interested in activities on social networks, without being very concerned about the other advantages provided by digital technologies. Anyway, the students who enjoy using multimedia resources during the learning process are also constant users of Internet services, which they use mainly for information, but also for activities on social networks (mainly instant messaging) – a fact also confirmed by previous studies in the literature [21,22,23].

CONCLUSIONS

Technology is only a tool that can improve the teaching process, but not only by itself. Those who are responsible for change are the teachers, who can improve the students' outcomes by using technology to convey knowledge, streamlining their methods, and perfecting themselves [24]. The concept of blended education facilitates such approaches and can trigger positive changes, satisfying for students, who will benefit from flexibility and comfort, and, consequently, also for teachers, who will have the satisfaction that their work achieves its purpose and that the information they transmit is properly heard and acquired.

Abstract: *The scientific and medical world is making permanent efforts to study, understand, and cure the complicated pathology of Systemic Lupus Erythematosus (SLE) – the disease with 100 faces, due to the diversity and complexity of the symptoms. SLE has a devastating impact on the patient's life, causing multiple metabolic imbalances produced by both the disease itself and the necessary medication. This case report addresses the therapeutic aspects of SLE and diabetes mellitus, on a 47-year-old male with a sensitive multi-pathology and aggressive evolution, medication, and approaching psychomotor rehabilitation therapy, up to now, when SLE treatment has ended. Also, this case study report highlights the importance of flexibility in the psychomotor rehabilitation strategy, in the context of a large range of factors that influence its definition.*

Keywords: *SLE - systemic lupus erythematosus, diabetes mellitus, medication, recovery therapy, psychomotor*

INTRODUCTION

The scientific and medical staff are making permanent efforts to study, understand, and cure the complicated pathology of Systemic Lupus erythematosus (SLE) [1-3]. SLE, an inflammatory autoimmune disease, also named the disease with 100 faces due to the diversity and complexity of the symptoms, has a devastating impact on the patient's life due to the multiple metabolic imbalances produced by the disease itself and the necessary medication [4].

The etiology of SLE is unknown, as are the possible disorders (but not necessarily) – hematological, nephrological, neurological, skin, and ocular, because of cellular and tissue damage [5-7]. There is no chronological sequence of SLE manifestations, even in the same patient. It is problematic to diagnose, hard to treat (due to the various symptomatology from minimum to severe), and difficult to continuously adapt the strategy of preserving psychomotor capacity, sometimes necessary to change in an abrupt way.

Diabetes Mellitus in the case of SLE is a particular situation with the need for continuous monitoring because it can be influenced by this long-term disease and its complex medication treatment [8,9]. Administration of insulin units and/or gliclazide must be dosed by the treating physician according to the particularities of the case [9,10]. It is well known that diabetes can be controlled with careful diet and weight monitoring, and physical exercise as a supplement to medical treatment. That is why we consider the good collaboration between family, patient, doctor, and physical therapist, alongside the regular medical checkouts for blood variables of vital importance. The medical approach therapy is individualized and customized to fit each patient's need depending on the type of disease and each symptom.

Reflection of the theme in specialized literature and conceptual boundaries

Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with multisystem involvement. It is triggered by deregulation of the immune system which, due to the autoantibodies produced, attacks the body's healthy cells and tissues. The clinical picture is very rich, it can affect several organs, it has an undulating evolution with periods of exacerbation and remission, and the forms of presentation are from clinical manifestations without life risk (affects the skin, and joints) to potentially severe forms (affects the patient at neurological, renal, cardiovascular level).

There are 4 types of lupus:

- Systemic lupus erythematous – is the most common form of lupus. The manifestation of the disease differs depending on the affected structures.

- Cutaneous lupus – manifests itself in the skin.

- Lupus induced by drugs – iatrogenic lupus occurs as a reaction to the administration of certain drugs.

- Neonatal lupus – is a particular form of the condition and occurs due to the transplacental transmission of anti-Ro antibodies from mother to fetus during pregnancy and can have skin, cardiac (the most serious being atrioventricular block), hematological, and neurological manifestations.

Symptoms can range from mild to very severe, and although they can be chronic, they usually come and go, with the disease having an undulating course.

The most common complaints are fatigue, altered general condition, fever, lymphadenopathy (inflammation of the lymph nodes), and joint and muscle pain. Almost any organ can be affected.

Skin-mucosal damage

It is present in approximately 70% of patients. The classic manifestation of acute lesions is the heliotrope rash, erythema in "butterfly wings" present at the level of the nasal pyramid and the cheeks (redness that extends from the nose to the cheeks, below the eye area), without affecting the nasolabial folds. Erythema can also spread to other areas exposed to UV radiation – forehead, chin, décolleté. Photosensitivity is another characteristic of lupus patients. Subacute lupus may initially present with erythematous lesions that, over time, become papulosquamous, mimicking psoriasis or lichen planus. Discoid lupus erythematosus can appear on the face, scalp, ears, arms, hands, and back, the erythema being followed by hyperkeratosis or atrophy. Discoid lupus can be a strictly dermatological lesion, without being accompanied by systemic manifestations [29].

There may also be alopecia, skin purpura, erythema, small red dots, urticarial eruptions, livedo reticularis, Raynaud's syndrome, and ulcerations of the fingers pulp. Mucous membrane lesions consist of frequently painless petechial and ulceration of the nasal, oral, and, less commonly, genital mucosa.

Musculoskeletal damage

About 90% of patients diagnosed with lupus will have joint pain, arthritis, or muscle pain at some point. The joints of the hands, fists, and then the large joints (knees, ankles, shoulders, elbows) are most frequently affected. They can be painful, swollen, or red, the damage is usually symmetrical. Unlike rheumatoid arthritis, lupus arthritis rarely causes severe joint deformities and is not erosive.

Hematological impairment

Anemia, thrombocytopenia, leukopenia with neutropenia or lymphopenia may occur within the disease or secondary to pharmacological treatment.

Cardiovascular damage

Pericarditis, myocarditis, and endocarditis can occur in this disease.

Lupus endocarditis, called Libman-Sacks endocarditis, has no infectious cause. Atherosclerosis occurs more frequently and develops more rapidly than in the general population.

Lupus patients can also associate antiphospholipid syndrome (SAFL), in which antiphospholipid antibodies are present (anti-beta 2 glycoprotein 1 antibodies, anti-cardiolipin antibodies, lupus anticoagulant).

The presence of SAFL causes thrombosis), and spontaneous abortions.

Lung damage

It can take the following forms: pleurisy, inflammation of the pleura, pleurisy, pneumonitis, interstitial lung disease, pulmonary hypertension, and pulmonary thromboembolism. These can cause coughing, dyspnea (choking hazard), chest pain, and hemoptysis.

Kidney damage (lupus nephritis)

Renal damage determines the severity of the evolution of lupus patients. One-third of patients have kidney damage, suggested by proteinuria or hematuria, serum creatinine is above the upper limit of the laboratory, and creatinine clearance is low.

Neuropsychological impairment

It is the least understood manifestation of systemic lupus erythematosus and one of the most severe. Among the neurological manifestations, we mention convulsions, severe headaches, peripheral neuropathies, cranial nerve damage, cerebral vascular accidents, acute meningitis, and chorea. Psychiatric manifestations include psychoses, cognitive dysfunction, anxiety syndrome, and mood disorders.

Gastrointestinal symptoms

The most common gastrointestinal symptoms are anorexia, nausea, vomiting, and abdominal pain, and may be manifestations of mesenteric vasculitis, peritonitis, pancreatitis, or secondary to the administered medication.

Liver damage is found in up to 60% of patients – hepatomegaly, increased liver enzymes, and hepatic steatosis. Up to 8% of patients develop retinal artery inflammation with thrombosis at this level. The conjunctiva and cornea can be affected by secondary Sjogren's syndrome [30].

Specific immunological abnormalities

The presence of autoantibodies that target their own structures. Antinuclear antibodies (ANA) occur in approximately 95% of patients but have low specificity and may be associated with other conditions (rheumatoid polyarthritis, autoimmune thyroiditis, autoimmune liver diseases, infections, neoplasms, or in healthy individuals). The most frequent antibodies encountered in SLE are the antibodies: anti-double-chain DNA (SLE specific, associated with disease activity), anti-Sm (SLE specific), anti-U1 RNP, anti-Ro, anti-La, anti-ribosomal protein P (SLE specific, appear in neurological, hepatic damage), anti-histones (occur in classical and drug-induced lupus), anti-phospholipids (characteristics of SAFL), rheumatoid factor (non-specific, occurs in many other autoimmune conditions, infections). Decreased serum complement fractions (C3, C4, CH50) are associated with disease activity.

As is the case with many chronic conditions, systemic lupus erythematosus (SLE) negatively affects the quality of life, due to factors such as depression, pain, cognitive dysfunction, and sleep disorders.

Despite a little-understood etiology, fatigue is associated with SLE in approximately 80% of cases, which leads to a decrease in the level of physical activity necessary to carry out usual daily activities and thus dramatically decreases the quality of life.

Physical medicine and recovery in Systemic Lupus Erythematous may involve physical therapy, occupational therapy, speech therapy, recreational therapy, or combinations thereof. The specialist doctor should coordinate the patient's care and be attentive to subtle changes in symptoms that may indicate periods of disease activity [32].

Ultrasound is a frequently used procedure to provide heat in the depth of the affected joint, but it should not be used in the presence of inflammation; locally applied ice is the preferred method for inflamed joints. When ultrasound is used to improve joint mobility, the application of ultrasound and joint movement should be simultaneous.

Hydrokinetic therapy is recommended for the mobilization of inflamed joints, due to the buoyancy that ensures the unloading of the joint and the soothing action of the warm water.

The cardiovascular and pulmonary systems can also be affected by lupus. We try to improve aerobic capacity through physical exercises and specific breathing exercises [31]. These exercises will also contribute to maintaining a strong bone system, as well as strengthening ligaments and joints. Regular practice of sports activities is particularly recommended for patients with lupus.

Occupational therapy has the role of helping the patient regain as much of his functional independence as possible, despite the problems caused by the disease. Activities of daily living are encouraged and may require training with special equipment, techniques, and procedures. These activities include feeding, dressing, bathing, grooming, grooming, and cooking in the home.

A safety assessment at the patient's home may be indicated. Occupational therapy can provide recommendations for equipment (for example bathtub bench, elevated toilet seat, grab bar) to increase the patient's independence and safety at home.

Patients who have neuropsychiatric complications due to lupus may have cognitive dysfunctions, with deficits in attention, language, and memory. The speech therapist can be helpful when a patient with systemic lupus erythematous has slurred speech, difficulty understanding speech, or difficulty speaking properly.

Because systemic lupus erythematosus is a condition that manifests itself episodically, through bouts of activity alternating with episodes of remission, it is important that the patient does nothing without consulting the rheumatologist who deals with his disease – thus, it will reduce the risk of triggering a set of activities.

Unfortunately, there is still no treatment that can cure lupus, but there are treatments that can improve the symptoms while prolonging the episodes of remission of the disease. Adopting a healthy lifestyle also contributes to increasing the quality of life of the lupus patient.

Other things that the lupus patient can do to improve their condition:

- To give up smoking, but also the consumption of caffeine or alcohol.
- To adopt a healthy, balanced diet, based on as many natural foods as possible.
- To rest enough.
- Follow exactly the treatment recommended by the doctor, even during periods of remission of the disease.
- To avoid exposure to the sun because ultraviolet radiation

increases the risk of triggering a flare-up of systemic lupus erythematous.

It is recommended to reduce exposure to UV rays (using creams with a minimum sun protection factor of 50, avoiding exposure to the sun), a diet adapted to the patient undergoing corticosteroid therapy (to prevent its adverse effects – diabetes, hypertension, dyslipidemia), quitting smoking.

To prescribe a drug treatment, it is essential to identify the type of organ damage and its severity.

Non-life-threatening damage (skin-mucous, musculoskeletal, serositis) is indicated for the administration of non-steroidal anti-inflammatory drugs, low-dose systemic cortico-therapy, and synthetic antimalarials.

Potentially vital damage (cardio-pulmonary, hepatic, renal, hematological, central nervous system) requires cortico-therapy in moderate or high doses, associated depending on the affected organ, with immunosuppressants, anticoagulants, anticonvulsants, or even biological therapy.

Systemic lupus erythematosus is a chronic condition with multisystem involvement that presents severe evolutionary potential. Currently, thanks to advances in the knowledge of mechanisms, diagnosis, and treatment, the 10-year survival rate of lupus patients is almost 90% [30].

MATERIALS AND METHODS

This review started with a case study and addresses the therapeutic aspects of SLE and Diabetes Mellitus of a 47-year-old male with a delicate multi-pathology and aggressive evolution, caused by both the diagnostic and the difficult approach of the psychomotor rehabilitation therapy when SLE treatment has ended. In this case study report, we approach the importance of the management of the disease combining not only the multiple therapeutic actions but also the proper medication and nutrition and the psychomotor rehabilitation [11]. The study includes stages of life-threatening biological depreciation, and treatment, until the present when the therapy is positively affecting the patient's quality of life.

We present the short version of the patient's clinical history:

- At 27 years old, he underwent surgery for Non-Hodgkin's Lymphoma, associated with polychemotherapy and radiotherapy, with good response, in remission and without any specific medication from 2003.

- No forms of SLE manifestation until 2017.

- The aggressive form of SLE debuted in September 2017, caused by an unstable lifestyle associated with many detrimental factors accumulated in the last 15 years: unbalanced alimentation (almost exclusively processed meat products/minced meats and semi-prepared products, and carbonated beverages), smoking, stress, lack of sleep, improper self-medication for diabetes mellitus, sustained effort.

- The SLE treatment itself begins in February 2018, the patient’s previous treatment included only medication for his symptoms - edema, hypertension, cytopenia, etc.

- In his delicate condition, with the complex ongoing treatment, the patient beneficiated from the support of his family, nutritionist, priest, and doctors which improved his mental state of being.

- The period 2018-2019 was an equilibrated one when the patient was under observation, good nutritional plan, and 3 weekly sessions of physical therapy.

- In February 2022 the patient gets infected with SARS-CoV-2 Covid 19 Omicron Type which lead to a 10 days hospitalization in the nephrology unit medical care.

- The clinical picture of the subject presented above starts from the aggressive debut in the autumn of 2017 until 2021. We mention that multi-pathology and all associated diagnoses are not included in this presentation.

We also mention that during this period of multiple hospitalizations, there were diagnosed multiple associated pathology such as Diabetes mellitus type 2 with established Diabetic Nephropathy, Hypertensive Nephropathy with Renal Impairment, Hyperuricemia without signs of Inflammatory Arthritis or Tophaceous Disease, Vulgar Ichthyosis, Glomerular disorders in systemic connective tissue disorders, other water and electrolyte disturbances not elsewhere classified, Anemia in other chronic diseases classified elsewhere, Non-inflammatory Pericardial infusion, Medication-induced Specific Polyneuropathies, Secondary hypertension of other kidney disorders, Ascites, Hypo-osmolality and hyponatremia, Chronic nephritis syndrome, etc.

Also, here are some additional landmarks: the dietary regimen consisted of predominant vegetarian and hypoglycemic food, water management with 500 ml more than the urinary removal, medical plant tea indication, measurement of food in carbs no more than 150 per day (50/50/50 for each meal) associated with the prescribed medication; glycemic test each day before meals with calculated insulin administration (rapid and long-acting insulin) and/or gliclazide.

The multidisciplinary team of doctors (diabetologists, nephrologists, cardiologists, and Physiotherapists) [12-17] followed the patient during all the periods.

Treatment of SLE with the administration of combined diuretic treatment: high-ceiling diuretics (furosemide), Vasopressin antagonists (tolvaptan), Diuretic thiazide and potassium-sparing (amiloride hydrochloride and hydrochlorothiazide), thiazide diuretics (hydrochlorothiazide) and immune-suppressive combination (cyclophosphamide, mycophenolate mofetil), cyclosporine and corticosteroids (prednisolone).

Evaluation methods

To carry out this research from the Physiotherapists point of view, we chose the following measurements and evaluation tests:

1. to assess the level of the peripheral inflammatory stage at the level of the lower limbs as well as that of the muscle mass of the subject, we performed the anthropometric-perimetry method for the ankle and calf.

2. to evaluate the degree of mobility of the lower limb necessary for functionality, we used the goniometric method for the ankle and hip joints.

3. to assess static balance, we used the simple bipedal balance test with eyes open with several penalties for imbalance for 5 minutes.

4. to assess dynamic balance we asked the patient to walk on a drawled line of 5 meters distance, eyes open, without imbalance, dizziness, or lateral support.

5. to evaluate the subject's effort capacity, we used the ergometric bike without resistance with heart rate measurement.

Description of the used methods

1. The patient is in the supine position, and the measuring tape is applied at the level of the ankle joint including the most inflamed area, measuring an average of the right/left ankles before the physical therapy program.

2. The patient lying on his back, and the goniometer is applied according to the goniometric measurement and evaluation standards of the ankle and hip joint for the flexion movement, before the physical therapy program.

3. The patient in the standing position with bare feet on the floor for better plantar kinesthesia, eyes open, is timed for how many minutes/seconds he can stand without imbalances, dizziness, or lateral support. The evaluation was carried out at the beginning of the meeting for static balance.

4. For dynamic balance, a 5m line was marked on the floor, and the patient was asked to follow the line walking, eyes open, marking any sign of imbalance, dizziness, or lateral support, evaluated in how many meters the patient succeed to go on, at the end of the session.

5. The patient on the ergometric bicycle without lumbar support, with a distance between the hip and the pedals so that the knee is slightly flexed, without load, he pedals freely at a slow pace, following the heart rate so that it does not exceed 120 beats/min, it is marked how many minutes he can pedal up to the indicated maximum cardiac effort, or any other sign of imbalance, dizziness, numbness or pain. The test was held at the end of the physical therapy session.

Evaluation Instruments

The used instruments were a tape measure, goniometer, stopwatch, liner, ergometric bicycle, and pulse tester.

Research methods used

The research methods used in the paper were:

- the theoretical documentation method.

- pedagogical observation.

- the experimental method.

- the method of tests and evaluation samples.

- the investigation method.

- the method of recording and statistical-mathematical data processing.

- the graphic method.

Applied intervention

To streamline and synthesize the process of describing exercises applied, they are presented below (Tables 1 and 2).

The tables show the means we worked with, the exercise program proposed for every period, and their dosage.

Teaching materials used to fulfill the improvement program of motor functional skills and of balance and effort capacity were the stick, a small hand weight 1 kg, a terra band, the balance board, the inflatable balance disc, the gym ball, the small spikes ball for prehension, the bicycle, marker.

The physical therapy program no. 1 consisted of this period in: specific exercises that do not involve risks factors for strokes, bruises, or bleeding; exercises that do not present risk factors for a patient with high blood pressure; exercises and techniques for lymphatic drainage; specific techniques for tone muscle and equilibrium; specifically adapted methods for connective flexibility and joints mobility; programs for developing effort capacity; outdoor adapted program; exercises that consider the electrolyte imbalance (already existing due to the disease); breathing exercises.

Table 1: The process of describing initial exercises applied – the first program

Type of method	Exercise	Series	Reps or seconds/minutes	Pause (sec)
Mobilization	From the lying position - slow passive mobilization of the ankle in all directions	3	30 reps	30 sec
	From the lying position - slow passive mobilization of the knee for flexion and extension	3	15 reps	30 sec
	From lying position - Slow passive mobilization of the hip in all ranges of motions from simple to complex	3	15 reps	60 sec
	From lying position and sitting - Active mobilization of the upper limbs with a stick in all ranges of motions	3	15 reps	60 sec
	From lying position - Free active mobilization of the upper limb in all ranges of motions	3	15 reps	30 sec
	From lying position - Free active mobilization of lower limbs in all ranges of motion (bicycle, shears, bypasses)	3	15 reps	60 sec
	Quadrupedal position, cat forward and backward	3	10	120 sec
Tone muscle	Lying position - all range motion mobility with 1-kg hand weights	3	15	60 sec
	Sitting position - all range motion mobility with 1-kg hand weights	3	15	60 sec
	Sitting position - terra band extension between arms in abduction and extension	3	10	120 sec
	Sitting position - leg extension with a terra band resistance	3	10	120 sec
	Lying position - knee flexion and extension with terra band resistance	3	10 reps	120 sec
Static balance	Sitting position - imbalance from the shoulders in all directions with the requirement to maintain the posture from the abdomen without the help of the hands	3	10 reps	60 sec
	Standing position - Keep abduction of the hands	3	10-60 seconds	120 sec
	Standing position - maintain the balance without lateral support or movements	3	10-60 seconds	120 sec
Dynamic balance	Standing position - Raise 1 leg on a support ball	3	10-60 seconds	60 sec
	Standing position - walking with a plastic cup with water in the hand	3	10 m	60 sec
	Standing position - walking on a drawled line on the floor without lateral support or lateral deviations	3	10 m	120 sec
	Standing position - with lateral or face hand support - on a balance platform or ball - back straight, crunches	3	10 reps	120 sec
	Standing position - lateral support - kick a ball	3	10 reps	60 sec
Effort capacity	Bicycle ride - level 0	1	5 min	-
	Bicycle ride - level 0	1	15 min	-
	Claiming stairs from 1 to 3 floors	1	15-30 min	5 min
Outdoor training	Walking outdoors on a parc with support (frame, cane or crutch, or human lateral support)	1	15-30 min	-
Breathing techniques	Lying position - costal and abdominal breathing techniques, slowly and following the dizziness or pain	1	5- 10 min	-
	Sitting position - gently inhale with the extension of the trunk and arms, and exhale slowly and long with the return and withdrawal of the navel towards the spine.	1	5-10 min	-
Manual techniques	Manual lymphatic drainage and pump exercises	1	15 – 30 min	-
	Manual therapy for connective tissues	1	15-30 min	-

All exercises and techniques were adapted to the daily dynamic state of functionality of the patient from very simple basic to the maximum possible in his case. The programs were carried out on an outpatient basis at the patient's home, with a frequency of 3 sessions per week (Monday, Wednesday, Friday), the duration of the session being between 30 and 120 minutes depending on the daily state of the patient and the applied methods.

Table 2: The process of describing initial exercises applied – the second program

Type of method	Exercise	Series	Reps or seconds/minutes	Pause (sec)
Mobilization	From the lying position - slow active mobilization of the ankle in all directions	3	30 reps	30 sec
	From the lying position - slow active mobilization of the knee for flexion and extension	3	15 reps	30 sec
	From lying position - Slow active mobilization of the hip in all ranges of motions from simple to complex	3	15 reps	60 sec
	From lying position and sitting - Active mobilization of the upper limbs with a stick in all ranges of motions	3	15 reps	60 sec
	From lying position - Free active mobilization of the upper limb in all range of motions with 1 kg hand weights	3	15 reps	30 sec
	From lying position - Free active mobilization of lower limbs in all ranges of motion with 1 kg leg weights (bicycle, shears, bypasses)	3	15 reps	60 sec
	Quadrupedal position, cat forward and backward	3	10	120 sec
Tone muscle	Face lying position - all range motion mobility with terra band	3	15	60 sec
	Sitting position - all range motion mobility with 1 kg hand weights	3	15	60 sec
	Sitting position - terra band extension between arms in abduction and extension	3	10	120 sec
	Sitting position - leg extension with a terra band resistance or 1 kg leg weights	3	10	120 sec
	Lying position - knee flexion and extension with terra band resistance or 1 kg leg weights	3	10 reps	120 sec
Static balance	Sitting position - imbalance from the shoulders in all directions with the requirement to maintain the posture from the abdomen without the help of the hands or with a ball or a weight of 1 kg in the hands	3	10 reps	60 sec
	Standing position - Keep abduction from 90° - 180° of the hands	3	10-60 seconds	120 sec
	Standing position - maintain the balance without lateral support or movements and keep a 1 kg weight on the hands	3	10-60 seconds	120 sec
Dynamic balance	Standing position - Raise 1 leg on a support ball with 1 kg leg weight	3	10-60 seconds	60 sec
	Standing position - walking with a 1 kg weight on the hand	3	10 m	60 sec
	Standing position - walking on a drawled line on the floor without lateral support or lateral deviations with a cup of plastic water in the hand or on the head	3	10 m	120 sec
	Standing position - with lateral or face hand support- on a balance platform or ball - back straight, squats or lunges	3	10 reps	120 sec
	Standing position - lateral support - kick a ball or roll a 1 kg leg weight	3	10 reps	60 sec
Effort capacity	Bicycle ride - level 1	1	5 min	-
	Bicycle ride - level 1	1	15 min	-
	Claiming stairs from 1 to 6 floors	1	15-30 min	5 min
Outdoor training	Walking outdoors on a parc with or without support (frame, cane or crutch or human lateral support)	1	15-30 min	-
Breathing techniques	Standing position - costal and abdominal breathing techniques, slowly and following the dizziness or pain	1	5- 10 min	-
	Standing or quadrupedal position - gently inhale with the extension of the trunk, leg, and arm, and exhale slowly and long with the return and withdrawal of the navel towards the spine	1	5-10 min	-
Manual techniques	Manual lymphatic drainage and pump exercises	1	15 – 30 min	-
	Manual therapy for connective tissues	1	15-30 min	-

The program contains breathing exercises from decubitus and sitting, easy mobilization exercises for upper limbs with the stick and weights no more than 1 kg, slow exercises for lower limbs at the bedside level, lymphatic drainage, progressive passive mobilizations, progressive active spine mobilizations, static and dynamic equilibrium methods, core and leg muscle tone exercises, home bicycle program from 0 weight, outdoor walking sessions. Monday and Wednesday were addressed to the indoor program and Friday evening (due to the ocular and skin problems in SLE) if the weather was proper and the state of the patient was a good one, was addressed to the outdoor program.

Objectives

The 1 physical therapy program followed the objectives of each period of the evolution of the patient's state.

The initial objectives of the treatment were those of:
- preserving life
- following developments in functionality and evasion of complications.

The main objectives were:
- Improve the quality of life
- Decrease in inflammation and lymph retention
- Preserve and gain flexibility
- Develop tone muscle
- Develop a functional effort capacity
- Obtain a good static and dynamic stability
- Maintain a good psychological state of mind and optimism with the patient and family.

The functional state of the patient translates into functional disability to service and personal care, unable to have an orthostatic position, seated posture, and displacement.

The physical therapy program no. 2 consisted of the same exercises as in the first period but improved and adapted to the new daily possibilities of the patient. Such as upper and lower limb mobilization in a full range motion and with resistance, static and dynamic balance improved techniques for outdoor walking without the support and on uneven terrain, effort capacity development on the bicycle with resistance, maneuverability, and coordination exercises.

The program contains breathing exercises from sitting and standing positions, mobilization, and tonus exercises for upper limbs with the stick and 1 kg weight, exercises for lower limbs at the bedside level and from standing position with terra band, abdominal and diaphragmatic exercises, equilibrium exercises with or without lateral support, progressive active mobilizations, prehension exercises, lymphatic drainage, and manual therapy, bicycle training, outdoor walking sessions.

All exercises and techniques were adapted to the daily dynamic state of functionality of the patient following the rule of "primum non nocere" [26].

Objectives

The 2 physical therapy programs followed the objectives of each period of the evolution of the patient's state.

The initial objectives of the treatment were those of:
- preserving the quality of life and existent functionality
- following developments in functionality and evasion of complications.

The main objectives were:
- Improve the quality of life
- Preserve and gain flexibility and connective tissue elasticity
- Develop tone muscle and regain muscle mass
- Gain a functional effort capacity for outdoor functionality
- Obtain good static and dynamic stability together with coordination skills
- Maintain an optimistic continuous psychological state of mind and optimism with the patient and family.

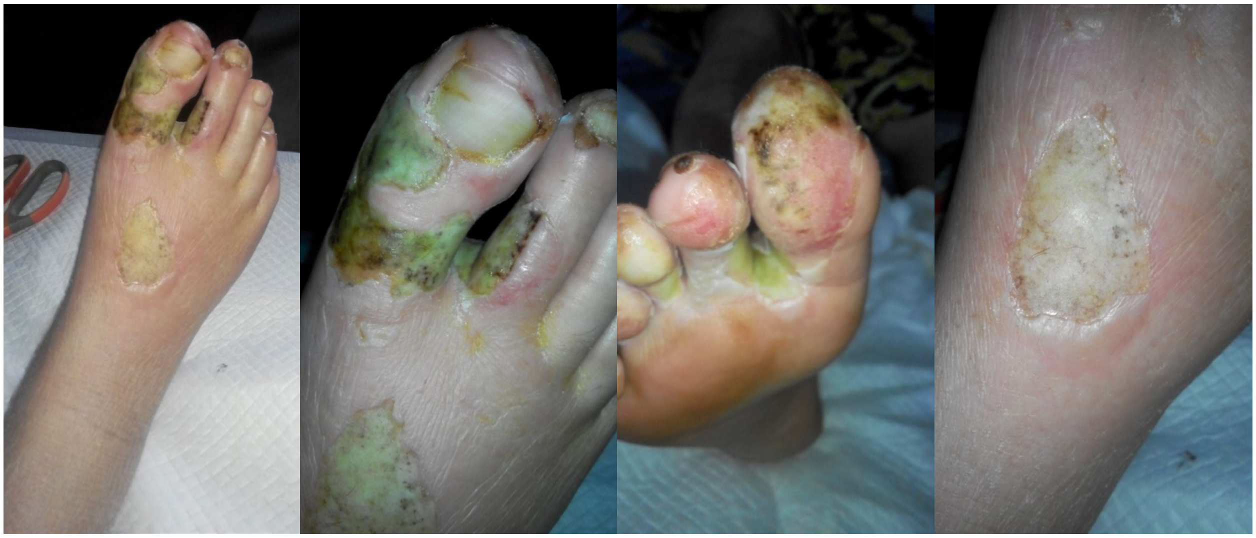

Figure 1: Representative images of the foot edema and neuropathy skin lesions

The recovery protocol consisted of tracking the functionality of each step according to the patient's evolution, following the food and drug indications and the degree of muscle and joint recovery, and also considering the equilibrium function that has been greatly affected.

During these months of complex treatment, the patient had positive or stagnant recovery moments, being affected by atmospheric pressure temperature, and climate change.

The purpose was to perform standing posture and walking with a moderate balance and state of equilibrium.

The functional state of the patient in March 2021 was that of functional and personal care integrity, the ability to perform standing posture, and walking with a moderate balance and state of equilibrium (Figure 3).

The patient continued the prescribed programs on his own at home during the pandemic period and the functional state of the patient in June 2022 was that of functional and personal care integrity, the ability to perform standing posture and walking with a moderate balance, and a state of equilibrium. (Figure 4).

RESULTS

The results concerning our patient were very promising (Table 3).

The perimetric measurements showed a constant decrease between the initial, intermediate, and final evaluations of the dimensions by 6 centimeters for the ankle joint and by 8 centimeters for the calf, relevant to a good drainage process both through the function of the kidney and through the lymphatic system, due to both effective medication and the sustained kinetic program.

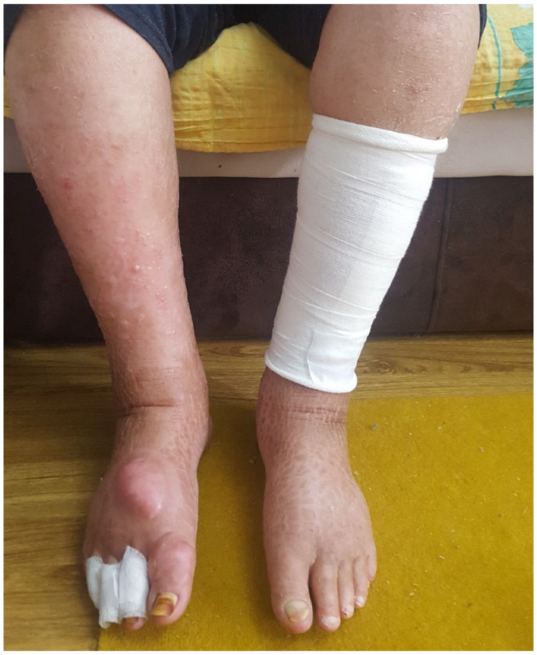

Figure 2: Representative images of the foot edema and neuropathy skin lesions

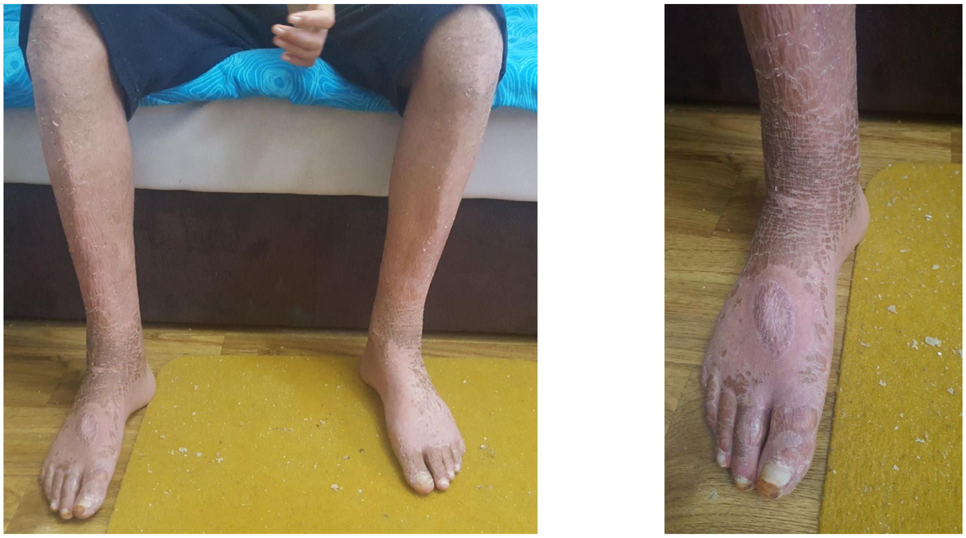

Figure 3: Representative images of the foot from March 2021.

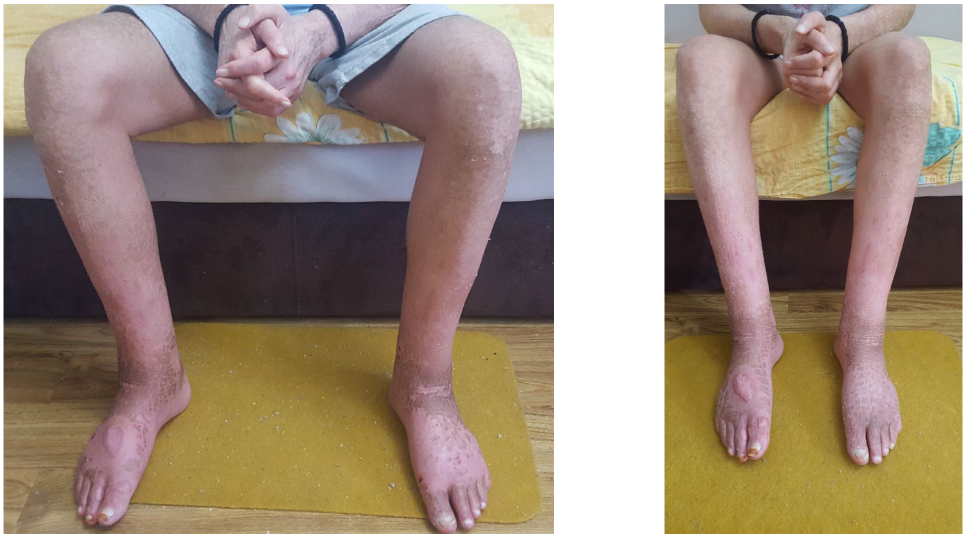

Figure 4: Representative images of the foot from June 2022.

The goniometric measurements for ankle and hip flexion had values of increased joint mobility, thus the ankle gained 10 degrees and the hip 55 degrees in a range of motion, which allowed the patient better mobility and dynamic functionality.

Table 3: Results of evaluation tests

Measurements	Initial testing Feb 2017	Intermediary testing Feb 2018	Final testing March 2019	Observations
Ankle perimeter	30 cm	27 cm	24 cm	Decreased by 6 cm
Calf perimeter	45 cm	43 cm	37 cm	Decreased by 8 cm
Ankle flexion mobility	5°	10°	15°	Improved with 10°
Hip flexion mobility	35°	85°	90°	Improved with 55°
Static stability	0	5 min	10 min	Improved 10 min
Dynamic stability	0	10 meters	30 meters	Improved 30 meters
Effort capacity	0	10 min	15 min	Improved 15 min

The evaluation of static stability recorded beneficial increases for the patient's life from the value of 0 minutes to 10 minutes without imbalance. The dynamic stability tests increased from 0 meters to 30 meters of walking without imbalance and support. Thus, the static stability gained 10 minutes without imbalances, and the dynamic one from value 0 reached a displacement of 30m without imbalances and support, which allowed the patient to go outside the house.

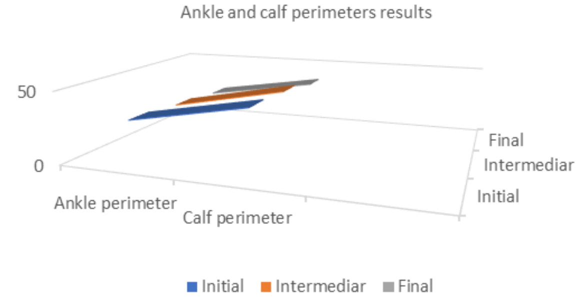

Figure 5: Ankle and calf perimeters measurements results

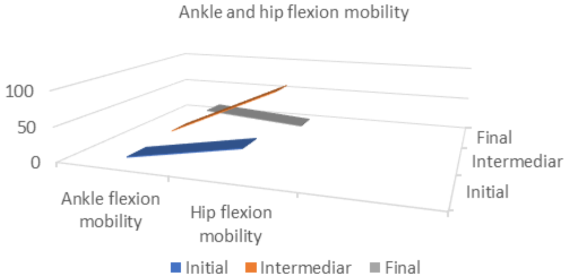

Figure 6: Ankle and hip flexion mobility results

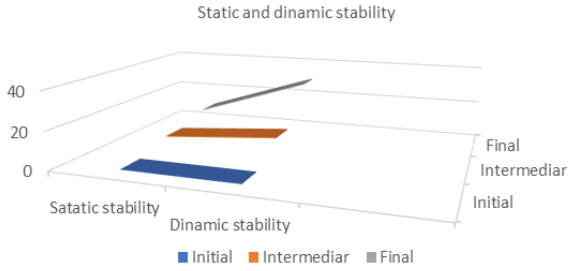

Figure 7: Static and dynamic stability evaluation results

The evaluation of the effort capacity from 0 initial value has reached 10 minutes without effort disorders so that later on the final evaluation on the best day of the patient will be 15 minutes without effort disorders. We mention that every day the patient's dynamics undergo changes from one hour to the next and the time of day matters a lot.

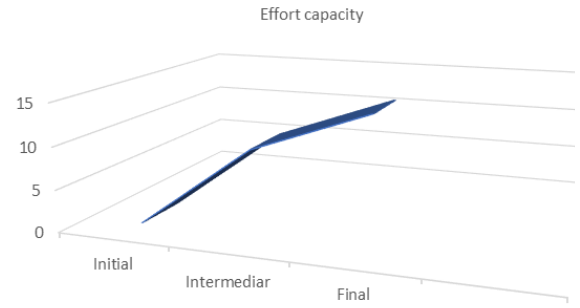

Figure 8: Effort capacity results.

DISCUSSION

The recommended strategy for addressing such a complex SLE case, for recovery of motor function, requires monitoring of at least three lines of observation:

1 Always be aware of disease progression (more in the context of risk of relapse of disease) and medication applied:

- Consulting physician recommendations, the results of medical tests, imaging investigations, etc.

- Check the treatment schedule, especially in the case of a disease involving a long-term treatment scheme with the adjustment of the substances and doses used (side effects of drugs can often have an impact on the patient's condition).

2 Use in an efficient manner the pluses of a positive psychic state (a calm, orderly mind with clear targets) and cultivate the will of the patient.

3 Permanent assessment of patient evolution, in points where difficulties were found: posture, coordination, and motricity.

Following the lines of this strategy, the physical therapist will be able:

- To work together with the patient, in a flexible system, the recovery exercises - maximum 10-30 minutes.

- To recommend to the patient a set of exercises to perform at home (immunosuppressive regimens do not recommend the presence of the SLE patient in the community over long periods of time, even more in the presence of other patients with transmissible diseases).

- And additionally, where appropriate, to apply therapeutic manual therapy and drainage sessions, as well as breathing techniques.

The recommended strategy for addressing the rehabilitation of motor function in such a complex case requires monitoring of at least these five levels of observation:

- Always be aware of the disease progression (even more in the context of risk of relapse) and medication administration, constantly consult physician recommendations, the results of medical tests, imagistic investigations, and so on. In this case, multiple impairments of the organ systems have led to chronic or acute manifestations of imbalances in the body [21-25,33, 34]. Permanently check the treatment schedule, especially in the case of a long-term treatment plan disease with the adjustment of the substances and doses used (side effects of drugs can often have an impact on the patient's condition).

- Permanent assessment of the patient’s evolution, in points where difficulties were found posture, coordination, and motricity, cause many of the associated diseases, both in the kidneys and other organs, make it difficult to choose the correct and balanced diet and medication.

- An important path leading to complete rehabilitation in this case, as in many others, was the combination of sustained social - psychological - spiritual support through faith and management with attention focused on the patient. The psychological support received from the medical staff and family, largely based on the patient’s trust in them, was even more necessary as the treatment with corticosteroids can cause changes in behavior (periods of extreme energy and activity, combined with periods of insomnia and irritability). We identified at least three main engines of the patient’s desire to recover – confidence in the attending physician and successful completion of the treatment, the desire to return to a normal life and sacred therapy.

The multi-pathology, as well as the delicate situation of the patient, have greatly raised the stakes of the entire medical staff in choosing the most suitable treatment management, which is still in progress daily.

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers may cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor may not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Editor-in-Chief. The Editor-in-Chief reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at: http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

– Accessible to the public at no charge;

– Searchable by standard, electronic (Internet-based) methods;

– Open to all prospective registrants free of charge or at minimal cost;

– Validates registered information;

– Identifies trials with a unique number; and

– Includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, a target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The Journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 200 words. Abstracts for original articles should be formatted as detailed in the word form. Titles must not be longer than 120 characters (including spaces). In every article, there must be three to ten pertinent keywords specific to the article yet reasonably common within the subject discipline.

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article. This should be cited as Rom. J. Mil. Med. (year); (vol): [issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related “miniseries” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this

avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are suggested to limit to 3000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Executive Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate.

Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication, as presented at http://www.ICMJE.org/.

Spelling

The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units

All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations

Abbreviations should be used sparingly and only where they ease the reader's task by reducing the repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: the title page; the main text file according to the word model.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or an article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented according to the word model. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 200 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. If appropriate, divide the abstract with the headings: Background and Aim, Methods, Results, and Conclusions. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to ten keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser – http://www.nlm.nih.gov/mesh/meshhhome.html.

Text

Authors should use the word form in editing the submitted material.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square parentheses in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or fewer; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

Use Index Medicus as the style guide for references and other journal abbreviations.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table and legend must be

understandable without reference to the text. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, •, ‣ should be used (in that order) and *, **, *** should be reserved for P-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication:

Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com. A cover letter containing an authorship statement should be included. The cover letter should include a statement covering each of the following areas:

– Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author. It is not accepted the idea of equal contribution.

– Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.

– A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

– For research involving pharmacological agents, devices, or medical technology, a clear Conflict of Interest statement about any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

– For clinical trials, these have been registered in a publically accessible database (see more under ‘ETHICAL CONSIDERATIONS (Further Information)’ later in these guidelines).

If the above items are not included in the cover letter, manuscripts cannot be sent for review. Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section ‘Parts of the manuscript’, including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using the word model that is to be found on the web page (http://revistamedicinamilitara.ro/wpcontent/uploads/2022/07/Macheta-articole.docx).

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, high-resolution figures (at least 300 d.p.i.) saved as .eps, .jpg or .tif files are required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted Articles

Accepted Articles are published online after final acceptance, and appear in PDF format only.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing the proof of acceptance. It is therefore essential that a working e-mail address is provided for the corresponding author.

COPYRIGHT, LICENSING, AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is submitted.

Abstract: *Erectile dysfunction (ED) has an intricate pathogenesis, with organic and psychosocial factors contributing to the shaping of its clinical manifestations and functional impairment. ED disrupts not only an individual's sexual life but may also contribute to impairments of self-esteem, social functioning, quality of life, overall well-being, mood, etc. The assessment process and therapeutic interventions should be adequate to the specific profile of each patient, therefore an interdisciplinary approach is usually recommended, in order to find the vulnerability factors, recent triggers, psychiatric and organic comorbidities or causes, and elements that contribute to maintaining the sexual dysfunction, such as lifestyle factors, interpersonal conflicts, or inadequate sexual education. This narrative review explores the evidence-based approaches to structured psychiatric, psychological, and therapeutical assessment in patients with ED, and the most validated psychosocial treatments available. The results support the use of recognized diagnostic criteria within DSM-5TR and ICD-11, together with structured instruments (scales, questionnaires, and inventories), in a multidisciplinary approach. The cognitive model and cognitive-emotional model of ED support the initiation of cognitive-behavioral therapy in these patients. Other interventions, like the PLISSIT model, sexual therapy, couple therapy, and sexual-focused psychoeducation are also supported by evidence. In conclusion, ED requires a combined, psychiatric, psychologic, psychotherapeutic, and organic-oriented assessment, with the purpose of tailoring the treatment to the patient's particularities.*

Keywords: *major depressive disorder, erectile dysfunction, antidepressants, antipsychotics, schizophrenia spectrum disorders, psychotherapy, psychoeducation*

INTRODUCTION

Erectile dysfunction (ED) is one of the most frequently reported sexual pathologies, with an estimated global prevalence varying from 3% to 76.5% [1]. The large variations in the reviewed reports regarding the prevalence of ED are explained by the method chosen during studies to define and quantify the manifestations of this disorder. When structured, validated clinical scales, questionnaires, or inventories were used, the prevalence of ED in young men was high [1]. Non-validated instruments have lower sensitivity, therefore the prevalence obtained using such tools is expected to be less accurate [1,2].

It is also important to highlight that ED was positively correlated with cardiovascular diseases, a high risk of all-cause mortality, mortality due to cardiovascular pathology, and a higher risk of developing dementia [1]. Further exploring this topic, ED is considered a "sentinel marker" for cardiovascular disease and could indicate a chronic and undetected coronary artery disease [2]. This correlation was supposed to be more significant in men with diabetes mellitus [2]. ED demonstrated significant value as an indicator of general health in men, irrespective of the cardiovascular risk factors [3].

Therefore, the importance of exploring the most adequate ways to diagnose and treat ED derives not only from the relevance of this disorder on the quality of life and well-being of the patients but also from the potential comorbid conditions this diagnosis may reveal during the multidisciplinary assessment.

OBJECTIVES AND METHODOLOGY

The main objective of this review was to find the most evidence-based assessment methods for patients with ED from the perspective of mental health professionals. Secondary objectives were founding data on (a) the available psychosocial approaches to ED; (b) ways to integrate psychological, psychiatric, and psychotherapeutic evaluations for patients with ED; (c) finding the key aspects that can help the training of mental health specialists in the evaluation and treatment of patients with ED.

The identification of relevant articles involved searching three electronic databases (PubMed, Cochrane, and Clarivate/ Web of Science) as well as their list of references. There was no inferior time limit for the search, while the superior limit was June 2023.

All primary and secondary reports were allowed into the analysis. No language restrictions were applied.

The paradigm used for retrieving sources was “erectile dysfunction” OR “male sexual dysfunctions” AND “assessment” OR “psychotherapy” OR “counseling” OR “diagnosis” OR “cultural aspects” OR “skills training” OR “mental health specialists”.

RESULTS

The results of the literature search were distributed in three sections, according to their relevance for each category of mental health specialists involved in the assistance of patients with ED. The accent is placed on the need to conduct a multidisciplinary exploration of the ED (Figures 1 and 2) and to formulate a therapeutic plan that takes into account the main vulnerability factors identified during the initial assessment of the patient.

The psychiatric approach

The diagnosis of ED implies, according to the 5th edition (revised) of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5TR), significant difficulty in reaching or maintaining an erection, or a marked decrease in the penile rigidity during erection, that appears on almost all occasions of sexual activity (75-100%) [4]. There is also the requirement of a minimal duration of 6 months for these symptoms, and they should cause clinical distress, in order to complete the diagnosis criteria [4]. Like in the case of all sexual dysfunctions, ED should be distinguished from organic, toxic, stress-induced pathology, or other mental disorders [4]. ED may be lifelong (if the patient did not have any period of normal sexual functioning) or acquired (if the dysfunctions started after a period of normal sexual functioning) [4]. ED can also be mild, moderate, or severe (depending on the level of symptoms-induced distress), or it may be generalized or situational (depending on the types of stimulation, situations, or partners that may or may not trigger the symptoms) [4].

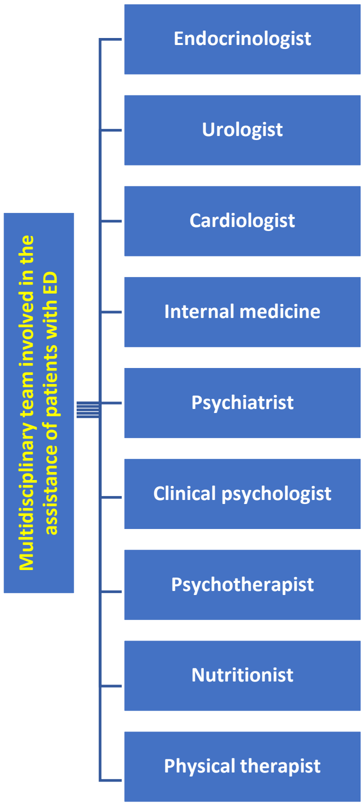

Figure 1: Multidisciplinary assessment of patients with ED

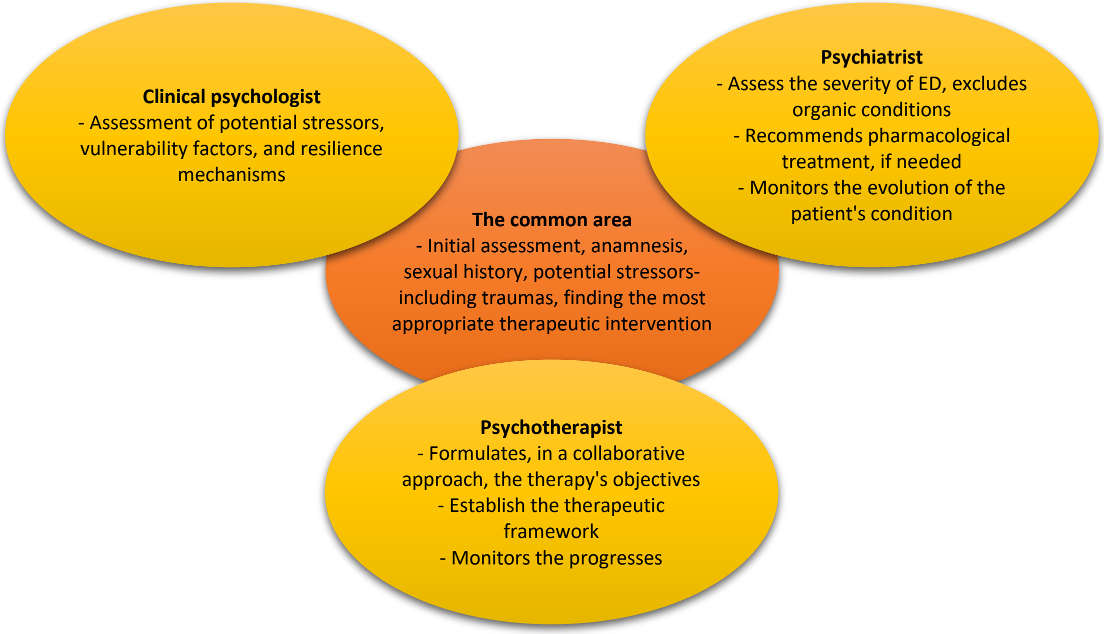
The diagnostic criteria in the DSM-5 and DSM-5TR changed from the previous versions (DSM-IV and DSM-IV TR) [4-7]. In these early editions, only two clinical criteria were mentioned, without any reference to the decrease of penile rigidity, as an independent criterion; also, no frequency of failed sexual acts was mentioned; no severity specifiers existed, but ED could have been classified as exclusively psychogenic or with mixed causation [6,7]. Further back, the third edition (revised) of DSM (DSM-III(R)) included the “male erectile disorder”, defined as a partial or complete, persistent and recurrent, incapacity to obtain and maintain the erection until the end of a sexual act, or recurrent/persistent lack of sexual excitation and pleasure during the sexual activity [8]. ED is included in the category of “male sexual dysfunctions”, together with delayed ejaculation, premature ejaculation, and male hypo-sexual desire disorder (Figure 3) [4-7].



Clinical psychologist
- Assessment of potential stressors, vulnerability factors, and resilience mechanisms
Psychiatrist
- Assess the severity of ED, excludes organic conditions
- Recommends pharmacological treatment, if needed
- Monitors the evolution of the patient's condition
The common area
- Initial assessment, anamnesis, sexual history, potential stressors- including traumas, finding the most appropriate therapeutic intervention
Psychotherapist
- Formulates, in a collaborative approach, the therapy's objectives
- Establish the therapeutic framework
- Monitors the progresses

Figure 2: The roles of the clinical psychologist, psychiatrist, and psychotherapist in the assistance of patients with ED

Erectile disorder
Male sexual dysfunctions
Male hypoactive sexual desire disorder
Premature (early) ejaculation

Figure 3: Male sexual dysfunctions [4-7]

The World Health Organisation’s Classification of Diseases (ICD) mentioned in its latest edition (ICD-11), that ED is the “inability or marked reduction in the ability in men to attain or sustain a penile erection of sufficient duration or rigidity to allow for sexual activity” [9]. Also, ICD-11 specifies that ED appears although the libido and sexual stimulation exist, and its manifestations may be episodic or persistent (several months), and associated with significant distress at the clinical level [9]. In the previous edition, ICD-10 (the version for clinical research), ED had as its main clinical characteristics (1) the impossibility of participating in sexual activity according to the desire of the individual, (2) the dysfunction appears frequently, but may not be observed on every occasion, (3) the manifestations have a history of at least 6 months [10]. The ED may manifest itself as: a complete erection that may be obtained in the initial stage of sexual activity, but then disappears before ejaculation (if this appears); erection may be detected, but only in situations where the sexual activity is unprepared; partial erection, insufficient for sexual activity; or complete absence of erection [10].

The psychiatric assessment of patients with ED is recommended to be carried out from both the clinician's perspective (focusing on signs and symptoms) and the patient's (focusing on the consequences of dysfunction). There may be significant differences between the two perspectives, depending on the criteria for defining ED, for example, the duration of the manifestations, the frequency of their occurrence, and the functional impact. Sometimes the patient can admit the presence of erectile dysfunction and the associated discomfort, but at other times he avoids mentioning any aspect related to sexual functioning, presenting only general symptoms - "weakness", "permanent fatigue", "lack of initiative", etc.

Sexual dysfunction can be an isolated symptom or it can be integrated into a complex context, as it may appear together with multiple psychiatric symptoms (such as anxiety, insomnia, depression, psychotic manifestations, and substance addiction) or organic manifestations (like urinary hesitancy, high blood pressure, pelvic pain, etc.).

Among the main differential diagnoses in ED, major depressive disorder (MDD) is important to be considered, because a decreased libido has been detected in these patients during the acute episodes, and some of the adverse events of antidepressants involve sexual functioning [11-17]. According to a systematic review and meta-analysis (n=49 reports), there is a high comorbidity rate of ED in patients with MDD (OR=1.39) and vice versa (OR=2.92), but a causal relationship can not be determined [11]. The incidence of sexual dysfunctions in patients undergoing treatment for MDD is difficult to be determined, but decreased sexual desire, decreased sexual excitement, reduced ability to reach orgasm, delayed orgasm, ED, delayed ejaculation, priapism, painful ejaculation, penile anesthesia were all reported in this population [12]. Therefore, sexual dysfunction may be a common MDD symptom, but also a frequent adverse effect of antidepressant treatment [14]. Due to this lastly-mentioned phenomenon, premature drug discontinuation in patients with MDD is not an uncommon event [14,18]. Nefazodone and bupropion have been associated with a lower incidence of sexual adverse events, due to their pharmacodynamic properties, unlike the selective serotonin reuptake inhibitors (SSRIs), which are among the most frequent drugs associated with such negative events [18]. At any rate, monitoring sexual adverse events during antidepressant treatment, as well as monitoring sexual functioning in these patients as part of the MDD clinical picture, are very important for preserving therapeutic adherence and quality of life [18-20].

Psychosocial stressors can trigger both major depression and erectile dysfunction [11]. Depression itself can reduce sexual functioning through multiple mechanisms (decreased initiative, fatigue, decreased self-esteem, ideas of uselessness and inability, etc.) [11-13]. Persistent erectile dysfunction can lead to reduced self-esteem, rumination about personal incapacity, and depression. In conclusion, patients with ED should be evaluated for signs of major depression and vice versa [11].

Psychotic disorders involve the presence of delusional ideas (some of which may have a sexual theme), hallucinations (some may be proprio- or interoceptive), thought and language disorganization, behavioral disorganization, negative symptoms (avolition, apathy, flat affect, anhedonia, alogia, etc.). Patients with psychotic disorders frequently associate sexual dysfunctions as a result of negative symptoms, antipsychotic medication, associated depression, etc [21-29]. In patients with psychotic disorders who had never received psychotropic treatment, 17% still accused the presence of sexual dysfunction [22]. Therefore, it is clear that not all sexual dysfunctions reported in this population are secondary to pharmacologic aspects, although a false causal relationship may be construed by patients, relatives, or even treating physicians. It must be mentioned that most mental health professionals do not ask their patients with psychosis about sexual dysfunctions, in clinical settings [23]. The sexual functioning in outpatients with schizophrenia spectrum disorders (SSD) has been associated with the level of subjective quality of life [24]. Also, a correlation between sexual dysfunctions in patients with SSD and their therapeutic adherence has been demonstrated, even when the dose, number, and duration of antipsychotics were not associated with the presence of sexual dysfunctions [25].

In an interesting study, patients with schizophrenia who were drug-naïve (N=20) were compared with patients who received long-acting first-generation antipsychotics (N=51) and with healthy controls (N=51), from the perspective of their sexual functioning [28]. Untreated patients with schizophrenia reported decreased sexual desire, while those who were receiving antipsychotics reported a restoration of the libido, although presented ED, orgasmic and sexual satisfaction problems [28]. Therefore, the structured assessment of sexual function is recommended to be conducted by mental health specialists in all patients diagnosed with SSD.

Anxiety disorders are included in the differential diagnosis of ED, but they may also be comorbid conditions with, or predisposing factors to sexual dysfunctions. While fear is the response to real or perceived imminent danger, anxiety is conceptualized as anticipating an unknown threat or an internal stressor [30]. Both anxiety and fear are associated with an activation of the sympathetic nervous system when anticipating an imminent danger, which prepares the individual for a fight or flight response [30-32].

One of the topics of interest for the current review is the presence of some specific phobias, like genophobia or erotophobia (fear of intimacy and sex), heterophobia (fear of the opposite sex), nosophobia (fear of microbes), coitophobia (fear of sexual intercourse), and haptophobia (fear of being touched by another person) [33-34]. These disorders may negatively affect the quality of sexual intercourse and even lead to avoidant behaviors.

Social anxiety disorder is characterized by fear of being evaluated or criticized by others when an individual is facing social situations, with severe negative consequences over all areas of functioning [35]. Unlike shyness, social anxiety disorder (or social phobia) has a severe impact on the quality of life in affected individuals [35]. According to a study (N=40 participants), men with social phobia report more frequent sexual dysfunctions and are more inclined to pay for sex [36]. The same study found moderate impairment in arousal, orgasm, sexual enjoyment, and subjective satisfaction with sexual activity in men with social phobia [36].

Panic disorder is defined by recurrent and spontaneous panic attacks, with significant negative functional impact [4-10]. Patients with panic disorder have a higher tendency to develop sexual dysfunctions vs. the general population [37]. According to a review (n=6 reports), panic disorder was associated with a high prevalence of sexual aversion and sexual infrequency, while untreated patients with panic disorder may have a higher risk of ED vs. controls [37]. Patients with panic disorder can perceive the similarity between the neurovegetative activation during sexual intercourse and the one with onset during a panic attack [38]. Therefore, this symptomatic overlap maintains a negative conditioning that leads to the continuation of ED [38].

Agoraphobia is characterized by the fear of enclosed spaces, although the focus of this disorder is not limited to such triggers (i.e., newer classifications also include the fear of open spaces, being alone outside the home or being in a crowd, and using the public transportation) [4-10]. The exposure to feared situations can trigger discomfort, anxiety, or panic attacks [4-10]. The exploration of this disorder during the psychiatric evaluation of patients with ED is important because of the significant impact this type of phobia has on the overall functioning and quality of social relationships.

Generalized anxiety disorder has as its core criterion excessive anxiety or worries related to various daily activities, occurring for at least 6 months, and this disorder has been frequently associated with sexual dysfunctions in men [4-10,39]. In a study that evaluated 64 men with ED or premature ejaculation, 23.4% presented with anxiety disorders, and generalized anxiety disorder was the most frequently detected [39]. Men with preexisting anxiety disorders had a higher probability of presenting performance anxiety related to sex and of being diagnosed with premature ejaculation [39].

The prevalence of anxiety disorders in patients with ED ranges from 2.5% to 37%, followed closely by depressive disorders (18-35%) [40,41]. This association was most frequently reported in patients aged between 45 and 54 years [42]. Anxiety, as a non-specific symptom, can impair both sexual functioning and interpersonal behaviors. But the relationship between ED and anxiety is bidirectional because sexual dysfunction can induce anxiety, and consequently lead to a decrease in self-esteem, performance anxiety, and social avoidance.

Obsessive-compulsive disorders (OCDs) are currently conceived as a spectrum, with core symptoms represented by obsessions, compulsions, or both, that occur over a significant period of time or cause discomfort or significant dysfunctions to the patient [4-10]. Individuals with OCDs often present problems with sexual functioning, and 6% of them report the presence of ED, while 39% are dissatisfied with their sexual functioning [43,44]. The specific treatment for OCDs may also play an important role in the onset of ED, starting from tricyclics to SSRIs, especially because this disorder may require higher doses of drugs than MDD or anxiety disorders [44,45].

Body dysmorphic disorder (BDD) is considered the result of a preoccupation with self-perceived defects in physical appearance, which are not observable by others, or are considered minor when evaluated objectively [4-10]. ED was more commonly reported in men with BDD vs. the control group, although libido, frequency of intercourse, and masturbation were similar in the two groups [46]. Patients with BDD had more concerns about their penis size and tried to use different methods to increase it [46].

Post-traumatic stress disorder (PTSD) occurs following exposure (direct or indirect) to life-threatening or severe physical trauma or sexual violence, which translates into intrusion symptoms, avoidance of trauma-related stimuli, negative alterations in cognitions and mood, and alterations in arousal and affectivity [4-10]. The risk of erectile dysfunction in PTSD patients was significantly higher than in the general population [47]. PTSD was associated with overall sexual functioning, sexual desire and satisfaction, and sexual distress [47]. Avoidance and negative alterations in cognition/mood were associated with a higher risk for sexual dysfunctions in this population [47]. Psychotropic medication for patients with PTSD was not significantly associated with the risk of erectile dysfunction [48].

The presence of a defined sexual dysfunction does not exclude the existence of comorbid disorders from the same category. This observation is supported by the results of a study in which 86% of the respondents to an online questionnaire who had a sexual dysfunction also reported the presence of another sexual condition [49]. Men with one severe sexual dysfunction were significantly more likely to have such comorbidities [49]. ED and premature ejaculation were comorbid in 23-29% of cases explored in this study [49].

Substance use disorders may frequently cause the onset of sexual dysfunctions. Alcohol, opioid derivates, cannabis, and ecstasy were associated with higher scores on tests of sexual dysfunction vs. controls in a clinical study (N=101 vs. 43 participants) [50]. The association was not significant for alcohol and cannabis ($p>0.05$), but opioid and ecstasy users had significantly higher scores on the International Index of Erectile Function (IIEF) vs. controls [50]. Patients with alcohol dependence have a 72% rate of being diagnosed with one or more sexual dysfunctions, the most common being ED, reduced libido, and premature ejaculation, according to another study that enrolled 100 male subjects admitted to a detox center [51]. Additionally, illicit substances are sometimes used as aphrodisiacs to enhance sexual performance or pleasure. However, existing data show that most drugs have negative effects on erection, libido, and ejaculation latency [50,51]. The data on cannabis use and its relationship with sexual functioning is controversial, because both men and women perceived this compound may increase their sexual functioning and satisfaction, especially desire and orgasm intensity [52]. Cannabinoids also have been associated with positive effects in a large variety of neurological disorders that may alter sexual functioning [53].

Pornography addiction or excessive use of online pornographic material represents a type of behavioral addiction with a potential negative impact on sexual functioning. There are several studies that have shown a high association between erectile dysfunction and excessive use of pornography, while other studies do not support this association [54-56]. Almost 60% of the patients with sexual dysfunction manifested when having intercourse with their partner, did not report this problem when using pornography [54]. However, a causal relationship between pornography and sexual dysfunctions does not exist, due to the lack of controlled studies and difficulties in designing such studies: sample biases, lack of clear diagnostic criteria, lack of validated instruments, the possibility that pornography abuse may be only a dimension of the more complex entity of sex addiction [54].

Cybersex is an excessive and uncontrolled use of online sexual activities leading to negative functional consequences [57]. Difficulties in forming intimate relationships have been associated with cybersex and pornography craving [58]. Men had higher scores for frequency of pornography online use than women and higher scores for craving the same materials [58].

Chronic organic conditions, such as diabetes mellitus (DM), blood hypertension, dyslipidemias, renal or hepatic failure, and endocrine pathologies (e.g., hypogonadism, hyperprolactinemia, hypothyroidism/hyperthyroidism) may all have an impact on sexual functioning [59]. Also, lifestyle factors such as smoking, chronic alcohol consumption, and excessive use of caffeine may be considered potential nocive stimuli on sexual functioning [59]. Neurological causes of ED that should be considered in the differential diagnosis are multiple sclerosis, spinal cord injuries, Parkinson's diseases, cerebrovascular accidents, etc., and the most common urological causes of ED are priapism, Peyronie's disease, and anatomical abnormalities [59]. The use of drugs like thiazides, spironolactone, clonidine, alpha-blockers, beta-blockers, antipsychotics, antidepressants, digoxin, ketoconazole, phenobarbital, etc. should be included among the potential triggers of ED [59]. Pelvic surgery and radiation therapy in the same area are other possible ED causes [59].

The pathogenetic factors of ED are traditionally split between psychological and organic, but this separation is artificial and, usually, there is mixed pathogenesis of this disorder in clinical practice (Figure 4). According to the results of a study focused on this distinction, in men ≤40 years old, approximately 85% had psychological causes for their ED and only 15% organic factors, while in men >40 years old, the rapport was 60/40 in favor of the organic causes [60]. Anxiety, depression, and relational conflicts were both causes and results of ED [60].

Predominantly organic ED

- Gradual onset
- Progressive evolution
- Constantly diminished response to sexual stimuli
- Better quality of erection while standing
- Elderly patients

Predominantly psychogenic ED

- Abrupt onset
- Intermitent evolution
- Loss of the ability to maintain erection
- Nocturnal penile tumescence is preserved
- Very good response to PDE5 inhibitors

Figure 4: Indicators of psychogenic nature vs. organic causes of erectile dysfunction

Still, the dichotomous model of organic vs. psychological causes in ED is outdated, and the currently suggested multidimensional model, which includes vulnerability factors and precipitating factors, is preferred [61]. This model involves the participation of (1) immediate factors, such as performance anxiety, (2) personal history variables, like recent traumatic events/stressors, and (3) vulnerability factors in childhood and adolescence [61]. Additionally, there are some important elements that should be integrated into the initial evaluation of patients with ED, related to vulnerability: rigid pattern of education in childhood, dysfunctional intrafamilial relationships, uncertainty about gender roles during early phases of development, lack of sexual education, personality disorders [62-64]. Between the most commonly reported factors that contribute to the onset of ED, in combination with vulnerability factors, are a large variety of interpersonal stressors (e.g., dysfunctional marital relationships, extra-marital relationships), psychological reactions to organic diseases, recent physical or mental traumas, occasional failure of erection [61-63]. There are also a variety of elements that maintain sexual dysfunctions, such as performance anxiety, guilt, habituation, fear of intimacy, an untreated sexual dysfunction in the partner, low self-esteem, etc. [61-63].

Sensitivity to sociocultural aspects is needed when patients are evaluated for any sexual dysfunction. Perception of sexuality varies from one population to another, and the impact of social or professional stressors may vary across different cultures [64,65]. Also, attitudes toward sex and the role of sexual activity are variables dependent on cultural context [65]. Gender roles are influenced by social and cultural factors, and they must be taken into account by practitioners when assessing patients with ED who are coming from another culture [64,65].

Studies exploring differences in sexual function and rates of sexual dysfunctions in homosexual and heterosexual populations are extremely few and their results are inconclusive [66]. ED in homosexual men was reported 1.5 times more frequently than in heterosexual individuals, according to a meta-analysis (n=4 studies) [66]. Homosexual men presented, in another study, a 45% higher risk of difficulties in obtaining an erection vs. heterosexual men [67]. Of these, 71% had little difficulty, 22% mild-moderate, 6% moderate, and 2% severe (according to IIEF-5 scores) [67]. Independent predictors for the presence of erectile dysfunction were age, a stable relationship, frequency of sexual activity with the partner, versatile sexual role, libido problems, ejaculation problems, and anodyspareunia [67]. Administration of phosphodiesterase-5 (PDE5) inhibitors was reported in 10% of homosexual men with ED, and 83% of them were satisfied with the effects of the medication [67]. Also, 43% used "legal drugs" to improve erectile dysfunction [67].

To conclude, the psychiatric evaluation of patients with ED involves the following steps: (1) formulating the diagnosis according to DSM-5 or ICD-11 criteria, based on an accurate collection of data on current mental and physical health status, personal medical history, and an assessment of vulnerability factors, triggers, and factors that maintain the sexual dysfunction; (2) verifying if there are concomitant sexual dysfunctions, besides ED; (3) exclusion of organic diseases, by recommending the adequate interdisciplinary and laboratory assessments; (4) formulating a therapeutic strategy, depending on the specific clinical aspects of the ED: psychotherapy, pharmacotherapy, or combined therapy. If non-psychogenic causes of ED or organic comorbidities have been identified, a multidisciplinary approach is recommended.

The psychological perspective

When evaluating a patient with possible ED, it is important to invite his partner to the initial interview, when possible, and to observe the dynamics of the couple's relationship [68]. The following aspects should be investigated during initial visits: fear of rejection, lack of satisfaction in the relationship, inappropriate sexual techniques, and sexual dysfunctions in the partner [68]. If one or more of the problems listed above are detected, the partner is invited to participate in psychotherapy [68].

However, there are also advantages to interviewing the patient alone: this way, it is possible to obtain a higher level of confidentiality, thus self-disclosure would be favored; various fantasies associated with guilt regarding his partner may be verbalized; aggressive sexual drives or traumatic personal experiences can be more easily revealed in the absence of the partner [68].

An example of structure for the first interview is the following: the couple can be interviewed for 10 minutes, to collect relevant historical data and establish the objectives of the assessment sessions; then each partner is interviewed separately, for 20 minutes; then the couple is brought together to formulate the conclusions [68]. Another assessment model considers the couple as the patient, and consequently, all assessments are made in the presence of both partners; the quality of the couple's relationship is a determining factor in the occurrence of erectile dysfunction and its resolution, therefore interviewing the couple is of paramount importance [68].

Forming an alliance with the patient is essential to a successful psychological interview, and to attain this result, the atmosphere must be safe, open, and non-judgmental; a strict agenda is not advisable, and flexibility is preferable [68]. The psychological assessment framework requires unconditional respect toward patients and an empathic, calm, and semantically adequate way to communicate with them [68,69]. The patient’s perspective on his own sexual dysfunction should be assessed and de-structured if based on myths or wrongfully understood scientific information [68,69]. The patient's personality needs to be assessed, as well as his core values, and attitudes towards life and others, his major existential goals, and the importance of relationships for the patient [68,69].

More specifically, the psychologist needs to assess the educational and cultural background of the patients, in order to formulate the questions and conclusions in an adequate manner; the main mechanisms of defense should be assessed, as well as his main coping strategies; gender identity disorders, sexual preferences, paraphilias, other sexual dysfunctions, childhood trauma (i.e., incest, rape, sexual or physical abuse) are essential elements to be evaluated; current level of functioning in all major areas is important to determine- actual relationships, professional performances, social support, relationships with nuclear family, hobbies; stressors in his current environment- bullying, mobbing, sexual harassment, discrimination, conflicts with peers; detailed analysis of the current sexual relationship; which are the main reasons for lack of satisfaction or failure in any functional domain?; dysfunctions in the main stages of the sexual cycle; factors that are associated with the onset and maintenance of the ED; how does it work a typical sexual intercourse for the evaluated individual?; which are the possible factors that negatively interfere with the stages of sexual cycle?; personal sexual history and possible relationship with the current problems [69].

The structured assessment of ED symptoms and functional consequences is done using validated psychological instruments. Arizona Scale for Sexual Experiences (ASEX) was developed by the Department of Psychiatry and Psychology at the University of Arizona and the Department of Psychiatry and Behavioral Sciences at Stanford University [70]. This instrument is self-administered, but it can also be completed during an interview, by a mental health specialist [70]. It measures the following dimensions: sexual desire, sexual arousal, penile erection/vaginal lubrication, ability to achieve orgasm, and orgasmic satisfaction [70]. There are two versions, one for women and one for men [70]. Each item is scored on a six-point Likert scale, with higher scores indicating greater severity of the respective sexual dysfunctions [70].

The Brief Sexual Function Inventory (BSFI) is intended for the evaluation of sexual dysfunction for men only [71]. This inventory has 11 items scored on a Likert scale, which assesses 4 dimensions - sexual desire, the ability to achieve or maintain an erection, ejaculatory function, and satisfaction with one's own sexual activity [71]. Low scores on this scale indicate high severity of sexual dysfunction [71]. For erectile dysfunction there are 3 items, scored from 0 (no dysfunction) to 5 (severe/ persistent dysfunction): frequency of partial/complete erections in the presence of sexual stimulation in the last 30 days; the presence of erections consistent enough to allow sexual intercourse in the last month; difficulty getting an erection in the last 30 days [71]. The scale is self-administered, although it was originally created to be administered by the clinician [71-73].

The UKU scale (Udvalg for kliníske Undersogelser) is an instrument for the assessment of adverse effects of psychotropic medication, sexual adverse events included [74]. It has 48 items scored from 0 to 4 on a Likert scale included in its first section; the second section comprises the assessment of the functional impact of the reported adverse effects; the third part refers to the management of the respective adverse effects [74]. The items represent symptoms and clinical signs distributed by categories: mental (difficulties concentrating, drowsiness, depression, etc.), neurological (dystonia, stiffness, tremors, etc.), neurovegetative (diarrhea, constipation, palpitations, etc.), and other (pruritus, increased/weight loss, photosensitivity, etc.) [74].

The scale also includes 6 items dedicated to sexual functioning: increase/decrease in sexual desire, erectile dysfunction, ejaculatory dysfunction, orgasmic dysfunction, and lack of vaginal lubrication [74]. The scale enables global assessment of the functional impact these symptoms may have [74]. The causal relationship between the medication and the adverse effect is also evaluated as being improbable, possible, or probable [74]. Low scores on this scale mean reduced severity of the respective manifestation [74]. It is administered by a clinician, but there is also a simpler self-administered form (UKU-SERS-Pat) [74,75]. All items can be applied or only relevant ones can be selected; the full version is recommended for clinical trials [75].

International Index for Erectile Dysfunction (IIEF) is a multidimensional tool for assessing sexual dysfunction and comprises 5 factors - erectile function, orgasmic function, sexual desire, sexual satisfaction, and overall satisfaction [76]. These factors result from 15 items formulated as questions, referring to erection frequency, erection firmness, penetration capacity, erection maintenance frequency, sexual satisfaction, etc. [76]. Items are scored from 0-5 and refer to the manifestations detected in the last few weeks; the instrument is self-administered [76]. The scores were used as indicators of the possibility of initiating sildenafil administration (scores below 14 out of a maximum of 30 in the "erectile dysfunction" domain) or psychosexual counseling (scores between 14 and 25 in the same domain) [76]. IIEF version 1 is only administrable to heterosexual men, but IIEF version 2 is applicable to both heterosexual and homosexual men [76,77]. A shortened 5-item version was also in use (IIEF-5), with a total score between 0 and 30; a high severity of dysfunction is present at scores 0–10; scores below 26 indicate the presence of some degree of erectile dysfunction [78].

Erectile Firmness Scale (EHS) contains only one item and is a self-administered instrument [79]. It rates the firmness of the erection from (0) (absent) to 5 (complete) and it is used in clinical trials to determine response to medication [79].

Still, the most important tool for the psychological assessment of patients with sexual dysfunctions remains a detailed history focusing on the history of sexual development. Aspects related to the partner's perception of sex life are essential for building an accurate picture of sexual dysfunction. All the scales previously mentioned are in no way meant to be a substitute for an accurate collection of personal history and psychological examination.

However, these instruments help the psychologist in detecting ED symptoms when patients are embarrassed to talk about the subject, and they are also useful for the monitoring process (i.e., effectiveness or tolerability of a drug or the efficacy of psychotherapy). They may also be needed for screening purposes in vulnerable populations. The main limitations of the scales are the lack of cross-cultural validation and possible differences in symptom reporting based on patient age [80].

The psychotherapeutic approach

According to the results of a review [60], the most frequently therapeutic intervention for ED is sexual therapy (50%), followed by cognitive-behavioral sex therapy (33%), while other types of psychosocial approaches have an equal representation (16%) – cognitive-behavioral therapy, group therapy, and couple therapy.

The psychotherapies dedicated to ED are derived from various interpretative models of this disorder. For example, the cognitive model of ED states that explicit/implicit requests for sexual performance lead to an expectation of performance (e.g., messages received from the partner create the expectation of an erection) [81]. In normal conditions, the attention of the individuals is focused on erotic stimuli, which increases the vegetative excitation, and favors the onset of erection (positive feedback); on the contrary, negative feedback involves catastrophic expectations, lack of perceived control over own body, focus of attention on partner's opinion about a potential failure or on other, non-sexual, stimuli, which increases the vegetative activation and focus on negative consequences, thus leading to ED [81].

The cognitive-emotional model of ED is based on a presumed occasional failure to obtain an adequate erection (no triggers are identified); following this random event, the individual activates cognitive schemata focused on personal incompetence and the misconceptions about the "macho" role; ruminations about future failures and an internal pressure to perform better next time is the following step; possibly as a defense mechanism that tries to protect the individual against a future failure, thoughts and images related to sexual activity disappear, therefore the stimulation decreases; the final stage is the "natural" consequence of the previous steps, and consists in ED's onset [82].

The main questions that help the therapist to formulate a treatment plan are: "What kind of phantasies and related emotions are associated with the current partner?", "Who has the initiative or how does the engagement in sexual activity appear?", "Is achieving sexual arousal within the current relationship and in general an easy process or a difficult one?", "How does the patient consider he can satisfy his partner and how does the partner perceive the satisfaction she receives?" [83]. Also, the therapist should explore the ability of an individual to achieve orgasm and under what conditions is it achieved; to verify what happens when one of the partners does not reach orgasm, and if this becomes a source of relational conflict; which is the definition of satisfactory sexual activity the same for both partners; to determine the level of satisfaction with sex life and with life in general in both partners [83].

According to other therapists specialized in sex-marital therapy, the specialist must keep detailed reports on the patient's status at each visit and of the suggested techniques; the therapist offers operationalized definitions of the problems he/she wants to elaborate on; the therapist evaluates the global functioning of the patient, not only of his sexual function; the therapist schedules monitoring visits at pre-determined intervals [84].

The PLISSIT model comprises "permission", i.e., the patients want to be considered "normal people", not "perverted", "deviant", "sick" or "abnormal"; often they are not disturbed by a certain behavior, but by the thought that they might do something bad or wrong; therefore, reassurance of normality is important for fantasies, thoughts, and dreams (e.g., those related to other people, or homosexual phantasies), for anxiety that can be associated with sexual stimulation (e.g., the appearance of spontaneous erections in inappropriate conditions); there are, of course, limits to validation, like fantasies with extreme sadism, pedophilic drives, etc. [85]. "Limited Information" is another core concept of this model that refers to the fact that clinicians provide limited information on relevant aspects of sexual concerns presented by the patient; the information is adjusted to the particularities of the patient, avoiding unnecessary scientific terminology and over-generalization; it is considered helpful in combating sexual myths [85]. "Specific Suggestions" refer to the fact that the therapist should formulate her/his suggestions according to the specific information obtained from the patient; these are direct attempts to change problematic behavior; these suggestions take place within the theoretical framework of short therapy [85]. "Intensive Therapy" includes specific techniques of sexual therapy [85]. During psychotherapy, the patient is encouraged to elaborate on the topic of his sex life [85]. The psychotherapist's attitude is one of empathetic listening and guiding the interview toward areas of interest in a discreet, non-confrontational manner [85]. The therapist is non-critical, normalizes, and helps validate the patient's emotions [85].

A frequently used technique in sex therapy is sensation focus [86]. These exercises progress from non-genital to genital tactile stimulation, with the instruction for the patient to refrain from vaginal penetration; thus, the patient's anxiety related to the sexual act will be reduced (desensitization), and the partner can be stimulated even in the absence of focusing on the genital area; after the patient has regained the confidence in himself, by managing to focus his attention on bodily sensations, penetration can be re-introduced into the therapy plan, gradually; it is recommended to formulate as objectives sensory focus sessions, 2 times a week, 10 minutes each; by changing roles between partners, each of them being active and passive, the patient gains experience in giving and receiving sexual stimulation [86].

Cognitive therapy and sexual fantasy training involve masturbation using guided imagery to regain control over erection, coupled with cognitive restructuring; homework includes scoring the satisfaction obtained by the patient and his partner [86].

Psychoeducation targets the increase of patients' level of information on the phases of the sexual cycle and encourages open discussions about sexuality [87]. This psychoeducational approach may have as an objective the modification of sexual scripts, which largely depend on social myths and misperceptions about sexual functioning [87].

CONCLUSIONS

The etiology of ED is usually mixed and, as a result, a multidisciplinary approach to both its diagnosis and treatment is recommended. Therefore, this review supports the conclusions of currently available guidelines for sexual dysfunctions, that a multidisciplinary, pharmacological, and psychosocial treatment is superior to monotherapy [86-88]. It is important for mental health specialists to approach the subject of ED in an empathic, non-conflictual, and non-judgmental manner, in order to obtain the information needed not only for the diagnosis but also for the formulation of the therapeutic objectives.

The main factors to be approached during the initial interview are the circumstances of the ED onset, vulnerability factors and triggers, sexual orientation of the patients, gender-related problems, and personal history of trauma [86]. Questionnaires and structured interviews are useful both initially and during the therapeutic process, as a way to document the evolution of ED symptoms. These assessment methods are selected according to the specifics of the case, but a combination of unstructured, structured interviews and scoring techniques using a validated clinical tool is preferred.

There are multiple psychometric methods for evaluating the severity of erectile dysfunction, quality of life, general functionality, etc., and the mental health specialist is the one who selects the most appropriate tools for each individual patient based on objective (severity of symptoms, functional impact), but also on subjective factors (personal experience). The stages of evaluating a patient with ED are flexible but generally involve a stage of constructing the psychiatrist/ psychologist/psychotherapist-patient relationship, describing the objectives and methods used for the evaluation, then a stage of investigating the sexual history, and a phase summarizing the collected data, which paves the way to a therapeutic solution. The desired outcomes of the therapy should be framed around satisfaction, pleasure, and quality, rather than quantity [86]. Directive and non-directive techniques can be combined depending on the particularities of the case. For an experienced mental health specialist, cultural, social, or psychological "barriers" can not represent major obstacles in the relationship with the patient. These aspects are discussed and re-interpreted through the lens of the objectives established by mutual agreement with the patient. The clinician is attentive to cultural, social, and educational details and integrates the patient's values into his/ her discourse. Active listening is essential to obtain "sensitive" information and to create an appropriate therapeutic framework.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research received no external funding.

Authors' contribution

OV conceived the idea of the review. OV, AGM, BMP, CAC, CFP and DU designed the study. OV, CFP, AGM, CAC, CFP, DU, MD, DGV, CN and CAS screened the studies during the primary search. OV, AGM, BPM and CAS drafted the first version of the review. OV, CAC, CFP, DU, MD, DGV, CN and CAS revised the manuscript and elaborated the conclusions of the review. All authors had full access to all data contained in the review and decided to submit the manuscript for publication.

Abstract: *Besides the motor and sensory dysfunction that characterizes multiple sclerosis, during the disease evolution and with the accumulation of new demyelinating lesions in specific areas of the central nervous system, autonomic dysfunction be-comes more prevalent among patients suffering from multiple sclerosis. Although not usually addressed, the complex spectrum of autonomic dysfunction manifestations has the potential of a negative impact on the daily activities of multiple sclerosis patients, needing specific investigations and therapeutic measures destined to alleviate symptoms and increase the quality of life. Since urinary dysfunction is evident from the early stages of multiple sclerosis on urodynamic studies even in patients without urinary complaints, it is indicated to thoroughly screen for urinary tract dysfunction as well as other autonomic dysfunctions in all the multiple sclerosis patients.*

Keywords: *autonomic dysfunction, urinary dysfunction, multiple sclerosis*

INTRODUCTION

Multiple sclerosis (MS) is one of the most common causes of disability in young patients. Clinically it does manifest uniquely for every patient, but depending on the site of the demyelinating lesions, some symptoms have a higher frequency in different combinations, particularly sensory symptoms, motor weakness, and bladder dysfunction. Most commonly, patients will present with numbness, tingling, diplopia, Lhermitte sign, and motor weakness, that last for at least 24 hours and may or may not resolve completely. Many patients may have residual symptoms, heat sensitivity with worsening of symptoms in case of increased body temperature, known as Uhthoff's symptom [1–3].

AUTONOMIC DYSFUNCTION IN MULTIPLE SCLEROSIS

As the disease follows its course over the years, inevitably patients will also experience damage to the autonomic nervous system with the involvement of both sympathetic and parasympathetic parts in different proportions. The promoters of the autonomic dysfunction appear to be lesions located in the nuclei of the periventricular regions of the fourth ventricle, medulla, but it was also seen in patients who presented cervical spinal cord atrophy with or without demyelinating lesions, suggesting that autonomic dysfunction may also result from axonal depletion [4].

Although severely overlooked, autonomic dysfunction has a great impact on the quality of life of patients suffering from multiple sclerosis, the most commonly addressed issues being bowel and bladder disturbances, which tend to be more bothersome in the case of longer disease, greater disability, or recent relapses [5].

Approximately 50% of patients experience orthostatic intolerance manifested by dizziness, loss of postural tonus, and tachycardia while transitioning from a supine to an upright position or in case of prolonged standing. The impaired sympathetic vasoconstrictor reflex responsible for maintaining normal blood pressure leads to an increased frequency of orthostatic hypotension among those patients[4].

Sleep disturbances in patients with multiple sclerosis are not very well studied, the most common symptom being difficulty initiating and maintaining sleep. There are several factors like muscle spasms, trigeminal neuralgia, restless legs syndrome, anxiety, depression, and side effects of medication used to treat fatigue, that contribute to insomnia, which can be searched for and addressed [2,4].

Another common but less addressed pathological aspect of multiple sclerosis is the sexual dysfunction that can be a consequence of multiple lesions including spinal cord lesions of the motor and sensory pathways and can be aggravated by the urinary incontinence and the spasticity accompanying upper motor lesions. About 50% of MS patients tend to become sexually inactive during the disease, with consequences like decreased libido, impotence, and infertility [2,5,6].

Bowel dysfunction is present in up to 50% of MS patients, about 43 % of them will complain of constipation partially due to disease exacerbations, and partially to decreased ambulation and certain medications that may alter bowel movement. A great proportion of patients with bowel dysfunction will present fecal incontinence as a consequence of impaired external anal sphincter function [2,4,7].

UROLOGICAL DYSFUNCTIONS

The most frequent autonomic dysfunction present in patients suffering from multiple sclerosis is bladder dysfunction, the prevalence of neurologic lower urinary tract dysfunction varies between 65 to 92% [8]. Approximately 75% of patients report bladder dysfunction secondary to a storage phase dysfunction leading to incontinence, or the voiding phase dysfunction leading to urinary retention and incomplete bladder emptying [2,4]. Bladder control requires complex coordinated functions of the cerebral cortex, pontine and sacral micturition centers, and the integrity of the peripheral nervous system [6]. The demyelinating lesions localized at the spinal cord level disrupt the fiber connections from the pontine micturition center to the parasympathetic sacral micturition center causing the silent C fibers, usually insensitive to bladder filling in normal conditions, to be hypersensitive leading to detrusor hyperactivity [9,10]. Spinal cord centers activate storage reflexes in the filling phase of the bladder, while the brain centers of micturition are responsible for the act of urine output [4,11]. Detrusor overactivity, which translates in clinical terms to symptoms like urgency to void that occurs at a lower bladder volume than normal, frequency or urge and incontinence are the leading complaints. On the opposite side lies detrusor sphincter dyssynergia described as detrusor contraction without urethral sphincter relaxation, which is responsible for the impossibility of bladder emptying causing symptoms like hesitancy, or interrupted stream. While the former urologic abnormality is caused by demyelinating lesions of the frontal cortex, the second one is a consequence of lesions of the pontine centers of micturition or lesions above the sacral parasympathetic centers [2,6,12]. Unlike spinal cord lesions due to multiple sclerosis, spinal cord injuries, even in patients with relatively preserved neurological function, are characterized by universal bladder dysfunction, meaning that there is an impairment of both sensation of bladder fullness as well as the motor control of bladder and sphincter [6,11].

For many patients, urological symptoms arise only in the later stages of disease progression with a proportion of over 50% of patients with severe MS presenting severe bladder symptoms, whereas only 5-10% of MS patients have mild bladder abnormalities at the beginning. Nevertheless, a retrospective study conducted in Ankara, Turkey demonstrated that 52% of their multiple sclerosis patients without urological complaints had altered urodynamic results which could be explained by a subclinical impairment [13,14].

Patients with overactive bladder syndrome usually complain of urinary urgency, increased daytime frequency or nocturia, and sometimes incontinence in the absence of urinary tract infections or other associated pathology that could explain the symptoms. Obstructive symptoms are also an important point of complaint especially when leading to urinary tract infections. These manifestations can be associated and can have a huge impact on patients' quality of life in terms of decreased quality of sleep, decreased work productivity, and depressive symptoms [15,16].

Urine retention is a consequence either of neurogenic underactive bladder or of detrusor sphincter dyssynergia causing bladder obstruction of urine flow, leading to frequent lower urinary tract infections that can be another cause of disease relapse through the autoimmune process which it sets off [9,17,18]. Regarding the complications of the upper urinary tract there have also been mentioned vesica-urethral reflux, hydronephrosis, and end-stage kidney disease have as consequences of the morphological changes in the bladder wall caused by high intravesical pressures [16,17,19–21].

EVALUATION OF LOWER URINARY TRACT SYMPTOMS

Urological evaluation should be specifically made for every patient considering their disease type and duration, the level of disability on the EDSS scale, comorbidities, and current medications especially opiates, antipsychotics, and antidepressants, starting with a complete history taking. The clinical dialogue should be directed towards describing urinary symptoms like frequency, urgency, hesitancy, retention, incontinence, and nocturia and the impact these symptoms have on the quality of the patient's life [16,22]. A bladder diary can provide additional information about the patient's habits of fluid ingestion and the exact frequency of bladder emptying [9].

Regarding physical examination, besides local inspection and examination of pelvic and genital organs including sacral cord mediated reflexes (bulbocavernosus, anal reflex), the neurologist should look for pontine, cerebellar as well as pyramidal signs which are indicative of lower urinary tract symptom severity [16,22]. For an initial evaluation of patients with multiple sclerosis, a bladder and renal ultrasound and a questionnaire for assessing overactive bladder and voiding dysfunction are in order, while for patients with red flags (recurring urinary tract infections, immunosuppressive treatment, EDSS >6, male patients, age >55) should be referred to a neuro-urology clinic or specialist [23].

Furthermore, some investigations can help us better understand the nature of the urological dysfunction. Firstly, all patients complaining of urinary symptoms should undergo a urinalysis and urine culture to assess the presence of a possible urinary tract infection as well as serum creatinine. Ultrasonography can allow us to measure the post-void residual volume, and it can be done at different times a day for better quantification of the bladder emptying pattern. Patients with a known high risk of upper urinary tract disease should benefit from periodical ultrasonography examinations for early detection of upper urinary tract dilation. Since a high post-void residual volume is not enough to distinguish between detrusor contractility problems and obstruction, urodynamic studies are required. Urodynamic studies represent a combination of cystometry and pressure flow study, useful in evaluating the outlet function and compliance of the detrusor and bladder. It can be used as a prognostic tool as well as for guiding the best treatment approach. In the case of hematuria, a urethrocystoscopy evaluation is required to rule out bladder tumors, bladder stones, and urethral stricture [16,20].

TREATMENT APPROACHES IN MULTIPLE SCLEROSIS-ASSOCIATED URINARY DYSFUNCTION

Physical therapy

One of the areas worth addressing is physical therapy, which in this case refers to physical exercises like pelvic floor exercises alone or combined with intravaginal electrical stimulation. Cognitive behavioral therapies may be helpful in some patients in trying to develop a bladder voiding schedule according to each patient's natural voiding pattern which combined with restricted water intake before bedtime can improve sleep quality and reduce complaints like fatigue [16].

Medical treatment

Regarding the drugs efficient for urinary dysfunction, there are several options depending on the main cause of dysfunction, that can be assessed by urodynamic studies. The first treatment line for neurogenic bladder is antimuscarinic drugs (oxybutin, tolterodine). Anticholinergics can alleviate complaints of neurogenic bladder as well as phosphodiesterase inhibitors and desmopressin which can be used as an alternative to antimuscarinics or as an adjuvant [6,20]. In an observational prospective study on the bladder and urodynamic alterations in patients with multiple sclerosis, the degree of urinary symptom severity decreased following symptomatic urological medication by lowering the bladder pressure, improving muscle spasms, and reducing pain caused by urine storage [24].

In case of bladder outlet resistance, autonomic dysreflexia, and postvoid residual volume, alpha-blockers (prazosin, terazosin) can help sphincter relaxation by lowering bladder pressure during contraction, but administered with caution because they can aggravate hypotension [6,20,25].

In patients with hypotonic bladders, cholinergic medications (bethanechol) may help empty the bladder, while in patients with pathologic relaxation of the vesical sphincter, alpha-adrenergic medication may increase bladder storage [6,17].

Minimally invasive treatment

Catheterization, self-catheterization, or third-party catheterization is the preferred method for patients who cannot otherwise empty their bladder. Patient medical education in managing a sterile intermittent catheterization can help reduce complications like urinary tract infections or bacteriuria. The habit of keeping a bladder diary can also help choose the frequency of catheterization so that the volume of the bladder at catheterization does not exceed 400-500 ml. As short-term methods, patients can dispose of condom catheters and adult diapers.

Botulinum toxin injections in the detrusor cause reversible chemical denervation with effects lasting for approximately 9 months, but also with known side effects like urinary tract infections, elevated postvoid residual volume, and increasing need for intermittent catheterization. In the case of bladder neck and urethral obstruction, to reduce the outlet resistance and to protect the upper urinary tract, patients may benefit from chemical denervation of the detrusor sphincter using botulinum toxin [6,17,20].

Surgical treatment

Sphincterotomy for reducing the bladder outlet resistance without completely losing the closure of the urethra comports the risk of secondary narrowing of the bladder neck and needs to be repeated at regular intervals. Bladder augmentation is indicated in patients with overactive or low compliance bladder when conservative methods have not been beneficial [20]. Urethral stents, sphincterotomy, and electrical implantation devices can be taken into account in selected cases, but with limited evidence of efficacy [6,26].

CONCLUSIONS

Multiple sclerosis is a central nervous system inflammatory demyelinating disease with multiple clinical manifestations, including autonomic dysfunctions. The most common and the most addressed is bladder dysfunction, but it is only a small part of the many bothersome effects of multiple sclerosis lesions, hence the need to evaluate and treat accordingly to ensure a higher quality of life for patients.

Abstract: *Background: Lung tissue changes following COVID-19 may persist for a long time after discharge and recovery, but not enough information is available about these chronic pulmonary sequels. We addressed to evaluation of chronic pulmonary sequels on CT scans of patients with COVID-19. Methods: This cross-sectional study was conducted on 94 patients with COVID-19 who were evaluated by CT scan at the time of discharge and also underwent continuous evaluation by CT scan of the lungs for at least three months. Through reviewing the hospital archive files, patients' backgrounds and three-month follow-up information were collected. Results: Chronic pulmonary involvement during the follow-up of patients was found in 83%. Peripheral and diffuse involvements were revealed in 79.8% and 3.2% respectively. Also, single-lobar and multi-lobar involvements were found in 69.1%% and 13.8% respectively. In terms of abnormal lung findings on CT scan, ground-glass opacity was found in 20.2%, Crazy-paving pattern in 2.1%, reticulation in 3.2%, parenchymal band in 12.8%, consolidation in 1.1% and bronchiectasis in 3.2%. The mean CT score was also 4.21 ± 3.45. The appearance of findings in CT patients was strongly influenced by the patients 'age, body mass index, underlying comorbidities, and also, the severity of initial COVID-19. Conclusion: Within at least three months of disease recovery in hospitalized patients with COVID-19, evidence of pulmonary involvement in 83% in the form of chronic pulmonary sequels can be expected. The most common findings related to pulmonary involvement included GOO in 20.2% and parenchymal band in 12.8% of cases.*

Keywords: *Chronic pulmonary sequels, CT scan, Covid-19*

INTRODUCTION

Although several effective vaccines with high immunity have been developed to prevent the spread of COVID-19, preventing its transmission is now believed to be the only way to combat the disease. In recent months, much effort has been published to explain the epidemiology, clinical manifestations, and clinical features and imaging of COVID-19 [1-4]. In this regard, the occurrence of fever and dry cough are the first and most common symptoms of the disease [5]. However, these symptoms are similar to those of other infections, such as the flu A and B, making it difficult to diagnose. Also, laboratory evaluation in patients is often time-consuming and its diagnostic kit may not be available for homogeneity. On the other hand, laboratory tests are sometimes associated with high levels of false negatives. In this regard, imaging plays a key role in the diagnosis and management of COVID-19-induced pneumonia. CT scan is the first diagnostic modality in patients with suspected disease and also a desirable protocol in following the effect and treatment process in these patients [6]. Especially in patients with a negative RT-PCR result, CT scan evaluation can be very useful [7,8]. Various studies have evaluated and described radiographic changes in the acute phase of COVID-19 disease and have correlated these changes with the severity of clinical manifestations [9-11]. Recent studies have also shown that about 94% of hospitalized patients still experience pulmonary parenchymal changes at discharge [12, 13]. In addition, some have shown that pulmonary opacities persisted in 53% of patients with mild COVID-19 without developing negative and complicating scaffolds for up to three weeks after discharge and clinical recovery [14]. Therefore, it seems that lung tissue changes, even the occurrence of pulmonary fibrosis, may persist for a long time after discharge and recovery of patients [15-17]. But not enough information is available about these chronic pulmonary sequels. What we addressed in the present study was the evaluation of chronic pulmonary sequels on CT scan of patients with Covid-19.

MATERIALS AND METHODS

This cross-sectional study was conducted on patients with COVID-19 who were admitted to our medical center during 2020 and 2021 and were evaluated by CT scan at the time of discharge and also underwent continuous evaluation by CT scan of the lungs for at least three months after treatment and recovery. Initially, through reviewing the hospital archive files, patients' background information including sex, age, history of underlying diseases, body mass index (BMI), and clinical characteristics of patients were collected. Also, in the initial CT scan of patients (during hospitalization) and also at the time of follow-up of patients (at least three months after discharge) and by an experienced radiologist, a complete interpretation of pulmonary involvement patterns was provided in terms of form and extent of involvement and CT score and classified according to the underlying characteristics of the patients. The severity of COVID-19 was stratified into four types mild, moderate, severe, and critical on the basis of patients' symptoms, laboratory results, and imaging findings at admission as previously described [18]. Pulmonary involvement was also assessed based on the type of lesion (peripheral or diffuse), the pattern of lobar involvement (single-lobar or multi-lobar), and the type of pulmonary lesions. To determine the CT score, each of the five lung lobes was visually scored on a scale of 0 to 5, with 0 indicating no involvement and 5 indicating more than 75% involvement. The total CT score was determined as the sum of lung involvement, ranging from 0 (no involvement) to 25 (maximum involvement) [19].

For statistical analysis, results were presented as mean ± standard deviation (SD) for quantitative variables and were summarized by frequency (percentage) for categorical variables. Continuous variables were compared using the t-test or Mann-Whitney test whenever the data did not appear to have normal distribution or when the assumption of equal variances was violated across the study groups. The categorical variables were compared using the Chi-Square test or Fisher's exact test if required. P values of ≤ 0.05 were considered statistically significant. For the statistical analysis, the statistical software SPSS version 23.0 for Windows (IBM, Armonk, New York) was used. Interventional studies involving animals or humans, and other studies that require ethical approval, must list the authority that provided approval and the corresponding ethical approval code.

RESULTS

A total of 94 patients were evaluated and followed up for at least three months after discharge. The average age of patients was 53.02±4.86 years ranged 40 to 62 years and 59.6% were male. The mean BMI was also 25.41±1.91 kg/m^2 and 5.3% were obese. Regarding comorbidity, 22.3% were hypertensive, 13.8% were diabetics, and 6.4% had a history of ischemic heart disease. With respect to disease severity, 4.3% were classified as mild, 86.2% as moderate, 6.4% as severe, and 3.2% as critical.

First, there was no evidence of pulmonary involvement in CT scans in 17.0% and therefore the frequency of chronic pulmonary involvement during the follow-up of patients was 83%. In terms of how the lesions were spread, 79.8% of the involvement was peripheral, and only 3.2% was diffuse. Also, single-lobar and multi-lobar involvements were revealed in 69.1%% and 13.8% respectively. In terms of abnormal lung findings on CT scan, GOO was found in 20.2%, Crazy-paving pattern in 2.1%, reticulation in 3.2%, parenchymal band in 12.8%, consolidation in 1.1% and bronchiectasis in 3.2%. The mean CT score was also 4.21 ± 3.45.

As shown in Table 1, the patterns of chronic pulmonary sequels in patients suffering from COVID-19 were independent of patients' gender. However, the pattern and distribution of pulmonary involvements were different in the younger and the elderly, and the diffuse and multi-lobar patterns were more found in older adults. Also, abnormal lung lesions were more prevalent in older patients. Totally, the mean CT score was significantly higher in older adults than in the younger. Similar patterns were revealed in obese as compared to non-obese patients and thus obesity was found to be another factor predicting more severity of chronic sequels on CT. As shown in Table 1, the presence of comorbidities was in line with more severe pulmonary expansion of abnormal lesions. Also, as indicated in Table 2, we showed diffuse and multi-lobar lesions as well as a higher rate of pulmonary lesions in those with more severe initial COVID-19 disease. There was also a significant association between CT score and disease severity (Figure 1).

DISCUSSION

In the acute phase of Covid-19, different patterns of pulmonary involvement are examined in depth and the severity and extent of the disease are classified accordingly. But the question remains, how long will these involvements last after recovery from the disease, and in other words, will there still be evidence of lung involvement due to the disease months after the symptoms have improved? Obviously, the presence of these abnormal findings in the form of chronic scoliosis in CT scans of patients, weeks and months after discharge from the hospital can indicate the continuation of clinical manifestation of the disease and sometimes even exacerbation of these symptoms. What we did in the present study was the evaluation of chronic pulmonary edema on CT scans of patients with COVID-19 and related underlying factors. First, the study showed that for at least three months after treatment and recovery from COVID-19 disease, evidence of pulmonary involvement would still be expected in 83% of patients even after improvement in clinical symptoms. The most common findings of CT as chronic disease sequels included GOO patterns in 20.2% and parenchymal band in 12.8%. Other findings included reticulation in 3.2%, bronchiectasis in 3.2%, Crazy-paving pattern in 2.1%, and consolidation in 1.1% of patients. Therefore, even after about three months of the disease and the relative recovery, the occurrence of some evidence in CT patients with COVID-19, especially GOO, is still predictable. Additionally, in terms of the pattern of involvements, the lesions are mainly in the form of peripheral, and in most cases, they will be single-lobar involvements rather than multi-lobar or diffuse ones. As a second finding, we found that the appearance of these findings in CT patients during the months following recovery from COVID-19 was strongly influenced by the patients 'age, BMI, underlying comorbidities (such as hypertension, diabetes, and history of ischemic heart disease) and also, the severity of initial Covid-19. In other words, the incidence of chronic pulmonary sequels in CT is more predictable in the months following recovery from COVID-19 at older ages, in obese individuals with underlying comorbidities, and in individuals with severe underlying COVID-19.

Various studies have reported the persistence of chronic pulmonary lesions in the weeks and months after discharge from the hospital, although due to differences in patients' underlying characteristics, different follow-up periods, and different intensities of underlying COVID-19 disease, CT scans were quite different during patient follow-up. In a study by Caruso et al and at 6-month follow-up, 72% of patients showed fibrosis-like changes and 42% of patients showed evidence of GOO [20]. In a study by Han et al., fibrotic-like changes were observed in 35% of cases, while 65% of cases either had completely clean lungs or had grand glass opacity or increased interstitial thickness. Age over 50, heart rate above 100 at admission, length of hospital stay over 17 days, respiratory distress syndrome, non-invasive mechanical ventilation, and CT scan score above 18 as factors associated with fibrotic-like changes over six months after discharge [21]. In another study by Dehan Liu et al during the first to third weeks, the GOO opacity and pulmonary fibrosis remained constant [22]. In a study by Safont et al., during a 180-day follow-up with a CT scan, 66% had chronic pulmonary lesions. Among this evidence, 68.3% had GOO and 38.4% had parenchymal bands [23]. In the study by Blanco et al., 19 patients with COVID-19 were evaluated by CT scan during a six-month follow-up period, in which only 48% had a normal CT scan [24]. Also, in the study of Hossein et al., 42.3% had pulmonary sequels in CT scan follow-up. The most common residual patterns in CT scans included GOO at 54.5% followed by grand glass mix at 31.8% and parenchymal bands at 13.7% [25]. Therefore, a wide range of findings related to COVID-19 can be seen in the weeks and months after recovery, sometimes without symptoms and sometimes with signs and symptoms associated with COVID-19. It seems that follow-up of these patients and simultaneous and continuous evaluation of lung CT scan findings along with clinical manifestations in patients will be necessary even after partial recovery and hospital discharge.

CONCLUSIONS

As a final conclusion, within at least three months of disease recovery in hospitalized patients with COVID-19, evidence of pulmonary involvement in 83% in the form of chronic pulmonary sequels can be expected. The most common findings related to pulmonary involvement included GOO in 20.2% and parenchymal band in 12.8% of cases. The presence of chronic pulmonary lesions in COVID-19 patients is strongly influenced by old age, obesity, the presence of underlying comorbidities as well and the severity of early COVID-19 disease.

Abstract: *Background: Silver-Russell Syndrome (SRS) and Beckwith-Wiedemann Syndrome (BWS) are two syndromes that are poorly diagnosed in many affected people due to mild and subtle symptoms, genetic complexity, and lack of familiarity with the hallmarks. Objective: The present study was conducted with the aim of determining mutations in H19, IGF2, CDKN1C, KCNQ1, and NSD1 genes in Iranian children suspected of SRS and BWS by the MS-MLPA method. Methods: In this case series study, which was conducted in 2022 in Pars Genome Laboratory, Karaj, Iran, 10 children suspected of SRS or BWS syndrome were included. These 10 Iranian children were referred by pediatric endocrinologists. 5 ml of peripheral blood was taken per patient for DNA extraction. MS-MLPA method was undertaken for possible mutations (methylation and deletion) in H19, IGF2, CDKN1C, KCNQ1, and NSD1 genes. Results: The interpretation of MS-MLPA results showed that out of 10 children (4 boys and 6 girls) suspected of having SRS or BWS syndrome (based on the pediatric endocrinologist's diagnosis), only 3 children were definitively diagnosed with SRS or BWS syndrome. Based on this, methylation changes in the promoter of ICR1 and ICR2, which are related to the genes H19, IGF2, CDKN1C, KCNQ1, and NSD1, lead to the development of SRS or BWS syndrome. Conclusion: The present findings showed that methylation changes in H19, IGF2, CDKN1C, KCNQ1, and NSD1 genes are associated with the occurrence of SRS or BWS syndrome. In this study, we show that MS-MLPA can serve as a rapid, inexpensive, and reliable method for the molecular diagnosis of these syndromes.*

Keywords: *Silver-Russell Syndrome (SRS), Beckwith-Wiedemann Syndrome (BWS), Methylation, MS-MLPA*

INTRODUCTION

Silver-Russell Syndrome (SRS) is a rare disorder characterized by intrauterine growth restriction, poor postnatal growth, macrocephaly, a triangular facial appearance, prominent forehead, body asymmetry, and significant feeding difficulties [1]. Patients can have a wide range of clinical findings. The majority of people with SRS have normal intelligence but have motor or speech delays. SRS is genetically heterogeneous, which means that different genetic abnormalities cause this disorder [2]. In around 60% of people with SRS, the disease is related to mutations in chromosome 7 or 11. Genetic defects that may be responsible for this syndrome include uniparental disomy of maternal chromosome 11P15.5, deletion of chromosome 7, or duplication of chromosome 7 or mutation of the KCNQ1, H19 (located on 11p15) and NSD1 (located on 5p35). However, in about 40% of patients with SRS, the cause is unknown. In general, the diagnosis of SRS is based on clinical findings. Since many symptoms are subtle and nonspecific, SRS remains difficult to diagnose [3]. Consensus guidelines for the evaluation and diagnosis of SRS have recently been published based on the Netchine-Harbison clinical scoring system for SRS [4]. Testing for known genetic causes of SRS (chromosomes 7 and 11) can confirm the clinical diagnosis in up to 60% of individuals. Knowing the main genetic cause can also help to select the appropriate treatment approach [5]. Treatment of this syndrome focuses on managing the symptoms [6,7]. SRS is present at birth and many symptoms improve as the patient grows [8].

Beckwith-Wiedemann Syndrome (BWS) is an overgrowth syndrome that affects certain chromosomes of the fetus. People with this syndrome may experience mild to severe signs and symptoms. One out of every 11,000 infants is affected by BWS, which is equally common in both boys and girls. This syndrome causes excessive growth of some body parts. BWS affects many areas of the body and makes the child appear significantly larger than their peers. Patients show different signs and symptoms depending on the affected organs [9,10], including macrosomia, hemihyperplasia, macroglossia, hypoglycemia in infancy, and sometimes long-term hypoglycemia (due to high insulin). The management of this syndrome focuses on its common symptoms and complications.

Physicians monitor and check affected children for low blood sugar and increase the frequency of feeding to obtain optimal blood glucose levels. There are several genetic causes of BWS, usually resulting in changes in one or more genes in a region of chromosome 11 known as 11p15 [11,12]. In most cases, there is genetic mosaicism. Other genetic changes in this syndrome include methylation defects in the region of 11p15, uniparental disomy (UPD) in 11p15, or mutation of the CDKN1C and IGF2. The diagnosis of BWS is clinical and it is often confirmed by genetic testing. To assay these abnormalities, a blood sample or other tissue samples should be taken [13,14].

In addition to organ growth defects, BWS patients are susceptible to other diseases, including cancer (such as Wilms' kidney tumor, hepatoblastoma, and neuroblastoma), heart disease (pericarditis, cardiomyopathy, etc.), hypoglycemia, hemihyperplasia, and digestive disorders [15]. Conducting investigations of H19, IGF2, CDKN1C, KCNQ1 (located 11p15), and NSD1 (located 5p35) genes in these syndromes and increasing information in this field can lead to a more accurate and precise diagnosis; preventing secondary diseases including cancer; and also be effective in preventing the transfer of these genes to the fetus before and during pregnancy [3,13,14]. Considering that no study in this field has been done in Iran, the present research aims to investigate mutations in H19, IGF2, CDKN1C, KCNQ1, and NSD1 genes in children suspected of SRS and BWS with Methylation-Specific Multiplex Ligation-Dependent Probe Amplification (MS-MLPA) method.

MATERIALS AND METHODS

Study procedures

In this case series study that was conducted in 2022 at Pars Genome Laboratory in Karaj, Iran, 10 children suspected of SRS or BWS were included. These 10 Iranian children were referred to us by a pediatric endocrinologist for final confirmation of the diagnosis. 5 ml of peripheral blood was taken for DNA extraction from these patients. MS-MLPA method was undertaken to identify mutations (methylation and deletion) in H19, IGF2, CDKN1C, KCNQ1, and NSD1 genes [16].

Inclusion criteria

The pediatric endocrinologists referred children under 12 years of age and clinically suspicious for the diagnosis of SRS or BWS. Written informed consent from parents and guardians of the children was documented.

Exclusion criteria

Children with multiple comorbidities

DNA extraction and purification

5 ml of peripheral blood was taken from each patient. DNA extraction from peripheral blood leukocytes was performed for all children using a DNA extraction kit (DENA Zist Asia, Cot.No:S-1031-1, made in Iran). Then, the quantity of extracted DNA was determined and confirmed with the nanodrop device, and the quality of the DNA samples was confirmed by using 1% agarose gel.

MS-MLPA

MS-MLPA probe mixture (ME030BWS/SRS) was purchased from the manufacturer (MRC-Holland, Amsterdam/NL).

This mix contains 42 probes, 26 of which are specific for the BWS/SRS region in 11p15. Ten of the 11p15 probes are methylation-specific since they contain a HhaI recognition site. Two probes for NSD1 and 13 reference probes (without HhaI recognition site) and one digestion control probe.

We used a total of 200 ng of genomic DNA extracted from peripheral blood by the salting-out procedure. 10 Mmol/l Tris-EDTA (pH 8.0) was added to DNA if dilution was necessary. After 16 h of hybridization at 60C, samples were equally split into two aliquots. The first aliquot underwent ligation only, whereas the second one underwent ligation followed by enzymatic digestion with HhaI [a restriction enzyme recognizing only unmethylated DNA] and PCR amplification using universal primers.

In the latter case, amplification products were obtained and detected by capillary electrophoresis only if the CpG included in the HhaI site was methylated. Ligation, enzymatic digestion, and PCR amplification were performed according to the manufacturer’s instructions.

All samples were run in duplicate and at least two normal samples were analyzed in each MS-MLPA experiment, as controls. PCR products (1 ml) were mixed with 0.4 ml of internal size standard (500LIZ Genescan; Applied Biosystems) and 9 ml of deionized formamide and injected into an ABI-3130 genetic analyzer (Applied Biosystems) equipped with a 36 cm, four capillaries array using POP7 as polymer. The samples were injected for 20 s at 1.5 kV and run for a total time of 1200 s at 15 kV. Genemarker v1.95 software is used for analysis, which performs all steps of data normalization and sloping data correction.

Ethical considerations

This study was approved by the ethics committee of Azad University of Tehran Medical Sciences (code: IR.IAU.PS.REC.1401.062). Throughout the study, researchers adhered to the Declaration of Helsinki. Written informed consent was obtained from the patients in this research. All information related to children was kept confidential. This study did not interfere with the process of providing medical services and care by physicians in the clinic. This research did not impose any additional costs on the patient.

RESULTS

The interpretation of MS-MLPA findings demonstrated that out of 10 children (4 boys and 6 girls) suspected of SRS or BWS (based on the diagnosis of a pediatric endocrinologist), only 3 were definitively diagnosed with these syndromes. None of the children were the result of a consanguine marriage. No deletion or addition changes were observed in any of the children, especially in the NSD1 gene.

The first patient

A newborn baby girl was diagnosed by an endocrinologist with suspicion of BWS. DNA was extracted from the blood sample and molecular analysis was done with MS MLPA genetic test. Copy number analysis showed that no deletions or duplications occurred in the chromosomal segments and therefore deemed normal (Figure 1A). Methylation analysis showed that hypomethylation of IC2 occurred in the 11p15 section [Figure 1B]. Therefore, this infant indeed had BWS.

B. Methylation analysis

Figure 1: MLPA genetic test findings related to the first patient

The second patient

A 21-month-old girl, with the examination of an endocrinologist, was diagnosed with suspected SRS. DNA was extracted from the blood sample and molecular analysis was done with MS-MLPA genetic test. Copy number analysis showed that no deletions or duplications occurred in the chromosomal segments, hence a normal finding (Figure 2A). Methylation analysis showed that hypomethylation of IC1 occurred in the 11p15 segment. This hypomethylation occurred in probes 19 to 22 (Figure 2B). Therefore, this baby definitely had SRS.

B. Methylation analysis

Figure 2: MLPA genetic test findings related to the second patient

The third patient

A 2-year-old boy was suspected of having BWS according to the examination of an endocrinologist. DNA was extracted from the blood sample and molecular analysis was done with MS-MLPA genetic test. Copy number analysis showed that no deletions or duplications occurred in the chromosomal segments and therefore, it was deemed normal [Figure 3A]. Methylation analysis showed that hypermethylation of IC1 occurred in the 11p15 segment. This hypomethylation occurred in probes 36, 38, and 39. IC2 hypomethylation was detected in the 11p15 segment. This hypomethylation occurred in probes 19 to 22 (Figure 3B). Therefore, this boy definitely had BWS. Uniparental disomy occurred in this patient and he inherited both chromosomes from his father.

The fourth patient

A 9-year-old boy was suspected of SRS according to the examination of an endocrinologist. DNA was extracted from the blood sample and molecular analysis was done with MS-MLPA genetic test. Copy number analysis showed that no deletions or duplications occurred in the chromosomal segments and therefore, it was deemed normal (Figure 4A). Methylation analysis showed a normal pattern in the IC1 and IC2 (Figure 4B). Therefore, this child did not suffer from either SRS or BWS.

Fifth to tenth patients

The fifth to seventh patients were a 5-year-old girl, an 8-year-old girl, and a 12-year-old girl, respectively, suspected of SRS. The eighth patient was a 4-year-old boy, the ninth patient was a 6-year-old girl, and the tenth patient was a 7-year-old boy who was suspected of having BWS; according to MS-MLPA, it was found that none had either SRS or BWS.

DISCUSSION

The main reason for investigating mutations and methylation changes in H19, IGF2, CDKN1C, and KCNQ1 (located on 11p15) and NSD1 (located on 5q35.3) genes lies in their function. Alterations in these genes affect function and can give rise to the phenotypes associated with SRS or BWS. The gene CDKN1C (Cyclin Dependent Kinase Inhibitor 1C) is a tumor suppressor and a strong inhibitor and a negative regulator of cell proliferation.

B. Methylation analysis

Figure 3: MLPA genetic test findings related to the third patient

Mutation in this gene can cause abnormal height and abnormal bladder structure and function. It also provides instructions for making proteins that help growth regulation [17]. NSD1 (Nuclear Receptor Binding SET Domain Protein 1) acts as a basic transcription factor and a regulator in transcription. Mutation in this gene can cause childhood acute myeloid leukemia and abnormal body height [18]. KCNQ1 [potassium voltage-gated channel subfamily Q member 1] gene belongs to a large family of genes responsible for making potassium channels [19]. The IGF2 gene (insulin-like growth factor 2) plays an essential role in the growth and development of the fetus before birth, and studies also showed that IGF2 causes the growth and division (multiplication) of cells in many different tissues [20]. The H19 gene is located near the IGF2 gene and provides instructions for making a non-coding RNA. Despite many genes, the H19 gene does not contain instructions for making a protein. The function of this non-coding RNA produced from this gene is unknown, but researchers believe it may act as a tumor suppressor. The H19 gene is highly active before birth in various tissues and appears to play an important role in early development [21].

The molecular defects of BWS and SRS are very heterogeneous. Many of these abnormalities involve epigenetic or copy number changes within the 11p15.5 gene cluster. Identification of these defects usually requires the use of multiple assays. Molecular diagnosis of SRS and BWS is currently possible only in one-third of patients [22] The aim of this study was to evaluate the methylation status and copy number of genes H19, IGF2, CDKN1C, KCNQ1, and NSD1 in blood samples of 10 Iranian children suspected of SRS or BWS.

Analysis of methylation, deletion, and addition in the mentioned genes in 10 children suspected of SRS or BWS, led to the diagnosis of SRS in one child and BWS in 2 children. In line with the present study, Gaston et al. showed that analysis of KvDMR1 methylation in leukocyte DNA alone identified BWS in 60% of all patients (64% of patients with severe form and 53% of patients with incomplete form of BWS). The analysis of the H19 gene methylation identified 13 other BWS patients with H19 hypermethylation, which confirms the effect of methylation in the occurrence of BWS in the two mentioned genes in line with our study [23].

Therefore, KCNQ1OT and H19 gene analysis is useful in routine evaluation and leads to the diagnosis of BWS or SRS in children suspected of these syndromes [24].

B. Methylation analysis

Figure 4: MLPA genetic test findings related to the fourth patient

Gaston et al. showed complete or nearly complete demethylation (KvDMR1 MI >90%) in 70% of BWS patients, but about one-third showed partial demethylation, suggesting that this abnormality can occur with mosaicism. These findings were supported by the analysis of other pathological tissues that show different demethylation patterns from blood cells. For example, KvDMR1 is incompletely demethylated in the tongue tissue samples of patients while it is fully demethylated in blood cells, indicating that the analysis of blood samples was sufficient to diagnose BWS [23]. Gaston et al., observed that demethylation of the KCNQ1OT gene was never associated with abnormal methylation of the H19 gene [23] except in patients with UPD 11p15, indicating at least two imprinting centers at 11p15.5. These findings were consistent with a recent study by Engel et al [12].

In the present study, the analysis of H19, IGF2, CDKN1C, KCNQ1, and NSD1 genes was normal in 7 out of 10 children. In line with these findings, Gaston et al reported that the analysis of KCNQ1OT and H19 genes was normal for 26 patients (26.8%). CDKN1C gene sequencing was performed in 10 of these patients [5 sporadic forms and 5 patients from families]. No abnormalities were found in sporadic cases. CDKN1C mutations were found in the families of 2 patients, and both patients had exomphalos [23]. Other unknown 11p15 abnormalities may account for other cases. Various mechanisms may cause over-growth syndrome by inducing the activity of growth factors such as IGF2. Several transgenic mouse models have provided evidence for this by showing increased levels of bioactive IGF2 induced by inhibition of the IGF type 2 receptor [IGF2R] or glypican 3, two agents known to bind and downregulate IGF2 expression, making it less accessible to the IGF1R [25]. Further studies on 11p15 genes and IGF2-related regulators in overgrowth syndromes should be conducted to determine the association between genotype and phenotype and to elucidate functional mechanisms.

In a study by Jurkiewicz et al., the MS-MLPA screening test identified the triplication of the IGF2/H19 domain for all probes of these genes in the ME030 kit, although this result was contrary to the results of our study because we did not find any duplication or deletion in individuals. They also showed that the H19 (ICR1) region had increased methylation and also showed normal methylation patterns for the IGF2R KCNQ1OT1 genes, which are in line with the results of our study [26].

In the present study, MS-MLPA was used for the molecular diagnosis of BWS and SRS. The results showed that MS-MLPA is a sensitive and reliable tool for further identification of molecular defects of BWS and SRS. These findings are in line with the study of Priolo et al., which was conducted in Italy [27]. Most epigenetic defects of BWS and SRS occur sporadically and exist in the mosaic form in individuals [28,29]. Therefore, it is important to use a sensitive diagnostic method to identify all mosaic cases. MS-MLPA method for the detection of 11p15.5 defects is very accurate and sensitive [27].

The great advantage of MS-MLPA is that this method simultaneously determines the copy number and methylation level of the loci. This is clearly shown in the third patient who had both hypomethylation and hypermethylation. While the ligation-only reaction revealed an increase in copy number, the ligation-digestion reaction provided information about the parental origin of the amplified region. Another study also confirmed that MS-MLPA can be considered a robust assay for the analysis of chromosome 11p5.5 defects [30]. In conclusion, our experience with these 10 suspected children showed that MS-MLPA is an easy, low-cost, and reliable method for the molecular diagnosis of BWS/SRS cases with im-printed and repetitive defects on chromosome 11p15. However, due to the small sample size as one limitation in this study, these results need to be confirmed in a larger series of patients. Also, for 7 children who were not confirmed to be suffering from BWS and RSS syndromes in this study, we suggest performing a WES test for them because the doctor may have made a mistake in diagnosing their symptoms and they may be suffering from another disease.

CONCLUSIONS

This was the first study to document these two syndromes in Iran. The present findings showed that methylation changes in the control regions of ICR1 and ICR2, which are related to H19, IGF2, CDKN1C, KCNQ1, and NSD1 genes, lead to the development of SRS or BWS. A diagnosis of the two syndromes is not accurate solely based solely on clinical symptoms and without the use of cellular and molecular genetic testing. MS-MLPA is suggested as a low-cost, reliable, and rapid method for the molecular diagnosis of BWS/SRS with imprinting and duplication defects on chromosome 11P15.

Conflicts of interest and sources of funding

The authors declare no conflict of interest.

Acknowledgments

The authors take this opportunity to thank all patients participating in the current study. Also, we acknowledge Pars Genome Laboratory staff in Karaj for their technical and scientific assistance.

Authors’ contribution

MAE, ME, OM, NS, and SS were responsible for the study concept and design. MAE, ME, OM, NS, and SS led data collection. MAE, ME, OM, NS, and SS were responsible for the analysis and interpretation of data. MAE, ME, OM, NS, and SS wrote the draft.

Ethics approval and consent to participate

This study was approved by the ethics committee of Azaz University of Medical Sciences [code: IR.IAU.PS.REC.1401.062]. Throughout the study, researchers adhered to the Declaration of Helsinki. Written informed consent was obtained from the children's parents in this research.

Patient consent for publication

Informed consent was obtained from all subjects involved in the study.

Abstract: *Body composition has been associated with better performance in military populations. However, there is no consensus about the most suitable body composition values for army paratroopers. To analyze body composition differences among the type of specialty, age group, and gender of army paratroopers, for a better improvement of their operability. 104 paratroopers of the Spanish Army were analyzed. Anthropometric and morphological data were analysed throw an In-Body720. There was a significant effect of age on intracellular water. Older soldiers had lower values of intracellular water, protein, and skeletal muscle mass than middle-aged soldiers. No significant differences (P ≤ 0.05) for the effect of the kind of work and age together or taken separately. Men had significantly higher values than women for height, weight, extracellular water, protein, fat-free mass, and skeletal muscle mass, and significantly lower values for the percentage of body fat, while no differences were found for body fat mass and body mass index. We conclude that paratroopers' body composition depends on age in skeletal muscle mass, intracellular water, and protein. For better unit readiness, soldiers must be monitored to analyze the effect of training and nutrition habits on their body composition.*

Keywords: *military; body fat mass; lean mass; body water*

INTRODUCTION

Physical training is a key factor for soldiers, who are expected to perform efficiently in physical tasks and maneuvers, i.e. lifting and carrying weights, deployments, long displacements, or fighting [26]. Traditionally, Body Composition (BC) has been associated with better performance in military populations [13], like in load-carriage jobs, in which lean mass (together with aerobic power) has been identified as more important than speed of movement [21]. Despite these facts, there is still a tendency towards considering perceived assumptions, like appearance, rather than empirical data to evaluate the capabilities of each soldier, and weight plus Body Max Index (BMI) by themselves are not enough to assess military training since many other factors, like lean mass gain, are positive aspects of training that need to be measured [22,24].

Although some standards have been used and considered in the Army to encourage soldiers to keep fit and with good nutritional habits, there is no consensus about the most suitable BC for all the healthy ranges of weight, soft lean mass, or body fat percentage. This attempt becomes more complicated if we consider the wide range of duties required by the different units of the Army and the different soldiers´ ages [14,28]. The incorporation of women in the Army further complicates this issue, because there is a need to define gender-appropriate standards to maximize female soldiers' health and performance [14]. Taking sports, as a reference, different specializations would require different standards of body composition [2,37], like different jobs would require different BC in the Army, as it was reported for the Army [16,17,38] and Air Forces [4]. Moreover, BC is a variable that could be easily managed by any motivated soldier both with good fitness and nutrition habits, with the aim, not to predict the performance, but to obtain health benefits, resistance to disease or injuries [18,27], and better general capabilities, both mental and physical due to a balanced lifestyle [14,25].

Paratroopers are considered an elite unit of the Army since their deployments are highly operational and involve a parachute jump, which has been reported to increase heart rate and decrease fine motor skills [10,34]. Apart from the physical readiness required for a quick setup, prior to entering the battlefield, they face additional hazards related to high altitudes, like hypoxia, disorientation, or night flights [3,5,6]. The principal tactical jumps are automatic para-chute jumps, in which the soldier has no control of the parachute opening, and manual parachute jumps, in which the subject has control of the parachute in all the maneuvers. Previous research found that both jumps produced a large stress response increasing cortisol, blood lactate, and sympathetic activation [8,10,11]. The health and performance of these kinds of units, which are under extreme psychological and physiological environments [7], can be undermined and there is a need to monitor their body composition [36], especially during their deployment in crisis management operations [29].

MATERIALS AND METHODS

Experimental approach to the problem

To implement the body composition assessment, we followed previous procedures [4,9,30] in which the participants stood upright on foot electrodes on the instrument platform, with arms not touching the torso. They were barefooted and without excess clothing. Four-foot electrodes were used, two of which were oval-shaped and two heel-shaped, and prior to testing the skin was cleaned and dried. Participants were asked to grip the palm and thumb electrodes. The system was calibrated before the testing session and the contacting surface of the electrodes was cleaned with alcohol before each measurement.

Participants abstained from alcohol consumption and vigorous exercise for 24h before the measurement and were measured in the morning after overnight fasting to control hydration status, as in previous research with bioelectrical impedance.

Subjects

A cross-sectional experimental design was conducted to analyze body composition differences of paratroopers, depending on their specialty, group age, and gender. 7 female paratroopers (specialty: automatic parachute; age: M = 32.1, SD = 8.79), and 97 male paratroopers were analyzed and classified into groups of specialty (43 automatic, age: M = 33.3, SD = 9.75; 54 manual, age: M = 34.8, SD = 7.58) and age (21 younger, under 29 years; 48 middle-aged, between 29 and 38 years; and 28 older, above 38 years) of the Spanish Army with a qualification of "fit" according to the periodic medical examination as recorded in the ministerial order 23/2011. Besides, during the research, they were carrying out the periodic aeromedical training included in the ministerial order 23/2011 and the STANAG 3114 "Aeromedical Training of Flight Personnel" (NATO regulations). Before starting the research, the experimental procedures were explained to all the participants, who gave their voluntary written informed consent under the Declaration of Helsinki. The procedures conducted in the present research were designed and approved by the Medical Service of the Aerospace Medicine Instruction Centre of Spanish Air Forces and the University Ethic Committee (CIPI/18/093).

Instruments

A bioimpedance analyzer (InBody 720, Biospace Co. Ltd., Seoul, South Korea) was used for body mass measurement (to the nearest 0.1 kg) and body height (to the nearest 0.1 cm). InBody 720 is a multifrequency impedance body composition analyzer, which uses an eight-point tactile electrode method to take readings from the body. It measures the resistance at five specific frequencies (1 kHz, 50 kHz, 250 kHz, 500 kHz, and 1 MHz) and reactance at three specific frequencies (5 kHz, 50 kHz, and 250 kHz) on each of five segments (right arm, left arm, trunk, right leg, and left leg). Bioelectrical-impedance analysis (BIA) is one of the methods available for measuring body composition in healthy populations. Its simplicity, portability, cost, and subject acceptance make it a very desirable technique. The reliability of BIA compared to the gold standard body composition measurement (DXA) has been successfully demonstrated for a wide range of normal and overweight populations [15,35] and military samples [1].

Data were electronically imported to Excel using Lookin'Body 3.0 software. The following parameters were analyzed: i. Body mass (kg), ii. Height (cm), iii. Body Mass Index (BMI) (kg/m^2), iv. Total Body Water (TBW) (kg) (including left and right arms, trunk, and left and right legs), v. Intracellular Water (ICW) (l) (including left and right arms, trunk, and left and right legs), vi. Extracellular Water (ECW) (l) (including left and right arms, trunk, and left and right legs), vii. Proteins (kg), viii. Minerals (kg), ix. Body Fat Mass (BFM) (kg) (including left and right arms, trunk, and left and right legs, in kg and %), x. Percentage of Body Fat (PBF) (%), xi. Soft Lean Mass (SLM) (kg), xii. Fat-Free Mass (FFM) (kg) (including left and right arms, trunk, and left and right legs, in kg and %), xiii. Skeletal Muscle Mass (kg).

Statistical analysis

The SPSS statistical package (version 21.0; SPSS, Inc. Chicago, Illinois) was used to analyze the data. Normality assumptions were checked with a Shapiro-Wilk test for all the subgroups and a Kolmogorov-Smirnov test for the whole group. Gender differences were analyzed for the same specialty (automatic parachute) with a T-Student test for parametric samples and a Mann-Whitney test for no parametric samples. Homoscedasticity was tested with the Levene test. A factorial ANOVA test was used to compare the type of work, the group of age, and the interaction between the type of work and the group of age on each parameter together with a Bonferroni post hoc test to analyze pairwise comparisons. The level of significance for all the comparisons was set at P ≤ 0.05.

RESULTS

The results are reported with their mean and standard deviation. Table 1 shows the results of body composition. No significant differences were found for the effect of type of work and age together, but there was a significant effect of age [F(2, 91)=3.172, p = 0.047, η2 = 0.06], in ICW. Older soldiers (M = 28.3, SD = 2.8) had lower values (p = 0.041) of ICW than middle-aged (M = 30.3, SD = 3.7). There was a significant effect of age [F(2, 91)=3.108, p = 0.049, η2 = 0.06], in protein. Older soldiers (M = 12.2, SD = 1.2) had lower values (p = 0.043) of protein than middle-aged (M = 13.0, SD = 1.6). There was a significant effect of age [F(2, 91)=3.154, p = 0.047, η2 = 0.07], in SMM. Older soldiers (M = 34.9, SD = 3.6) had lower values (p = 0.041) of SMM than middle-aged (M = 37.5, SD = 4.9).

Table 3 shows the results of body water (total, intracellular, and extracellular) by body segments. No significant differences were found for the effect of type of work and age together, but there was a significant effect of age [F(2, 91)=3.314, p = 0.041, η2 = 0.06], in the ICW of the trunk. Older soldiers (M = 13.3, SD = 1.51) had lower values (p = 0.035) in the ICW of the trunk than middle-aged (M = 14.2, SD = 1.71). Men had significant higher values than women for height (p=0.000; M = 176.9, SD = 6.6 vs M = 164.1, SD = 5.9), weight (p=0.000; M = 78.0, SD = 12.2 vs M = 60.0, SD = 6.8), TBW (M = 47.2, SD = 5.8 vs M = 34.0, SD = 2.1), ECW (p=0.000; M = 17.6, SD = 2.1 vs M = 12.8, SD = 0.73), ICW (p=0.000; M = 29.5, SD = 3.6 vs M = 21.2, SD = 1.3), Protein (p=0.000; M = 12.7, SD = 1.5 vs M = 9.2, SD = 0.6), Minerals (p=0.000; M = 4.4, SD = 0.62 vs M = 3.27, SD = 0.27), FFM (p=0.000; M = 64.4, SD = 8.0 vs M = 46.5, SD = 2.96), SLM (p=0.000; M = 60.7, SD = 7.5 vs M = 43.8, SD = 2.76), SMM (p=0.000; M = 36.5, SD = 4.8 vs M = 25.7, SD = 1.83), and significant lower values for PBF (p=0.034; M = 16.8, SD = 6.0 vs M = 22.0, SD = 4.3). No significant differences were found for the effect of gender between men and women in BFM (p=0.955; M = 13.5, SD = 6.5 vs M = 13.4, SD = 4.3) and BMI (p=0.065; M = 24.8, SD = 3.29 vs M = 22.34, SD = 2.9).

DISCUSSION

This study aimed to analyze body composition differences between the type of specialty, age group, and gender of paratroopers.

The first hypothesis was fulfilled since there were no differences in body composition between specialties. The second hypothesis was partially fulfilled since there were differences in intracellular water, protein, and skeletal muscle mass between middle-aged and older soldiers. The third hypothesis was not fulfilled since there were no significant differences in body composition between male and female paratroopers.

The main parachute jumps conducted by paratroopers' units are automatic or manual. The characteristics of both jumps are different since in automatic parachute jumps there is a lack of parachute control during the flight and especially during the landing (with high impacts that directly affect the muscle and bone structures of jumpers).

On the contrary, in manual jumps the flight and landing phases allow for greater control by the jumpers, leading to a less traumatic landing. But independently of these differences, we did not find differences between jump specialties, a fact probably due to the similar training, instruction, and nutritional regimen of both groups. The only difference was the tactical maneuvers after both jumps, but the rest of the preparation and military context were similar in both groups.

Differences between ages were found in intracellular water, protein, and skeletal muscle mass. The middle-aged group had a better mean than the older group in all those variables. Since the skeletal muscle is mainly built upon protein and water, these results show a tendency towards skeletal muscle loss with age.

The differences found could be related to the fact that middle-aged soldiers have complete growth, they are in their most operational phase in the unit, where they perform a higher number of jumps and the training is more intense, facts that could explain the higher intracellular water, protein, and skeletal muscle mass. This fact would join, with the investigations that support that resistance training promotes an increase in body water, principally by intracellular content [32]. On the other hand, older and younger participants perform a lower number of jumps: older paratroopers begin with the natural muscle mass loss process associated with age [33] and the younger paratroopers have not yet reached their growth zenith and their training in the unit is not yet maximum.

It is important to note that body fat mass, percentage of body fat, and soft lean mass, which have been usually reported as crucial for the performance of the units [13,21] were not different between groups, supporting the idea of the adequate habits of these troops during their service. Also, data analysis for body segments, reinforces the idea of the correct BC maintenance of these units, throughout their military service, despite their age, since no significant differences were found between groups of work and age.

Besides, if we compare the values of body mass index (24.12 kg/m^2 vs 25.88 kg/m^2 for age <28, 25.89 kg/m^2 vs 26.94 kg/m^2 for age between 28 and 38, and 24.64 kg/m^2 vs 26.86 kg/m^2 for age > 38); and body fat percentage (16.0% vs 16.6% for age < 28, 17.8% vs 18.8% for age between 28 and 38, and 17.2% vs 19.7% for age > 38) with some US Army standards, they are better for all the age groups [20]. Nevertheless, we should bear in mind that these groups are considered “elite” inside the Spanish army, and we are comparing them with a combination of soldiers from the combat support, combat arms, and combat service support units. However, results of body mass index and body fat percentage were higher than those reported for soldiers after 6 months of deployment in a crisis management operation (25.89 kg/m^2 vs 24.50 kg/m^2 and 17.8% vs 13.7%), a fact that highlights the need to monitor body composition during field activities, and especially on those with higher length, intensity or more stressful type [36]. Not only fat mass but fat-free mass and protein could be undermined during operational training or deployment [23,24].

If we compare these results with other Army units, body mass index and percentage of body fat are quite similar to airplane and helicopter pilots, but lower to other aircrew support members (25.49 kg/m^2 and 23.79% respectively) [4]. If we take body segments, there is a tendency towards having more fat-free mass in the right arm, which is consistent with previous research in the Air Forces [4], light forces [12], and even in females [39], which could be due to the prominence of right-handedness.

Regarding our third hypothesis about differences in BC according to sex, most of the BC male parameters in absolute terms were higher, while BFM and BMI did not show significant differences. Further investigation is recommended on this issue since the female sample size does not allow the values to be extrapolated and generalized.

Finally, regarding body water composition, there are no significant differences between age groups and manual or automatic parachute jumps in any of the variables analyzed, total, intracellular, and extracellular water. These values suggest an optimal balance of hydration among the healthy population and are correlated with a lower and healthier BMI [19], consequent with the normal-weight distribution among age and type of jump. Indeed, similar values of intracellular and extracellular values have been found in professional athletes depending on their composition whether it is an athlete or not [31].

The main limitation of this study was the small sample size of women. Secondly, we did not have permission to gather other demographic data (like nutrition, economic, education, and physical activity levels in leisure time) that could have helped us to better understand the differences between groups. These background variables could be studied further to design longitudinal research to understand the mechanisms of BC changes.

CONCLUSIONS

Paratroopers' Body Composition is not affected by their type of parachute specialty (automatic or manual) but depends on age for skeletal muscle mass, intracellular water, and protein. Older soldiers had lower values of ICW than middle-aged. Older soldiers had lower values of protein than middle-aged. Older soldiers had lower values of SMM than middle-aged. This data suggests good nutrition and training habits among the paratroopers. When comparing these data with previous research, it suggests that the body fat percentage of paratroopers is similar to airplane pilots, lower than aircrew personnel and combat and service soldiers, but higher than soldiers deployed. Body composition should be monitored to analyze the effect of training and nutrition habits during service, especially during stressful deployments. These facts must be considered to better prepare each unit.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research received no external funding.

Acknowledgments

We would like to acknowledge the contribution of the Aerospace Medicine Instruction Centre of Spanish Air Forces (Centro de Instrucción de Medicina Aeroespacial, CIMA), including the colonel, the military instructors, and the medical service personnel for their excellent work and collaborative spirit towards the present research.

Authors' contribution

Abstract: *The assessment of coping mechanisms in patients diagnosed with oncological diseases is essential for mental health specialists, who have to design the most appropriate case management strategy for comorbid mood disorders, anxiety disorders, adjustment disorders, and other psychiatric conditions that may be detected in this vulnerable population. The adequate treatment of these disorders is important for the preservation of mental health status, quality of life, and overall functionality in patients diagnosed with cancer. Coping mechanisms modulate the vulnerability toward psychiatric disorders, but they also have an impact on treatment adherence, which is an important factor correlating with prognosis. Appraisal-focused, problem-focused, emotion-focused, and occupation-focused coping represent the most well-defined strategies patients use when confronted with a stressful life situation, like a diagnosis with potentially vital consequences. Maladaptive coping strategies may also be identified in these patients, e.g., withdrawal from reality, including complete or partial denial of the disease, substance abuse, behavioral addictions, refusal of the recommended treatment, etc. The psychotherapeutic approach in patients with oncological diseases should include an initial evaluation of the coping strategies used either currently or in the past stressful conditions, an assessment of all the psychosocial resources the patients have (e.,g., support group, professional insertion, hobbies), and screening for mood and anxiety disorders that may have been triggered by the cancer diagnosis. Consequently, within the psychotherapeutic framework, a trained specialist can enhance the role of adaptive coping strategies and highlight the disadvantages of dysfunctional ones. This process may possess a favorable impact on treatment adherence, mental health status, and quality of life in patients with cancer.*

Keywords: *coping mechanisms, treatment adherence, quality of life, cognitive behavioral therapy, executive functions*

INTRODUCTION

Coping mechanisms are defined as thoughts and behaviors activated when finding a solution to either internal or external stressful situations is required [1]. These triggers may vary from different feared situations, a perceived lack of control over own impulses, or difficult life decisions (when internal events are taken into consideration), to physically traumatic stimuli, imposed changes in lifestyle, or interpersonal stressors (when external events are the focus of attention). Combined, internal and external triggers, may exist, as in severe physical conditions, such as oncological diseases, when the diagnosis, the treatment, the stigma, and the overall functionality (personal, familial, social, and professional) are all affected.

A traditional difference exists between the „coping mechanisms", which are conscious and voluntary, and the „defense mechanisms", which are psychodynamically-based constructs, and by their definition unconscious. Coping mechanisms represent sets of structured, stable responses that have a well-defined adaptive function [1]. Defense mechanisms, on the other hand, have as their purpose to disguise internal impulses, in order to protect the Ego; therefore they operate outside the sphere of the conscious mind [2-5]. However, not all authors agree with the assumption that all defense mechanisms are unconscious, because of examples like suppression or humor, which involves, at least partially, a participation of the Ego [6-8]. At any rate, it is considered that defense mechanisms act as „conscious suppression”, and this may be observed in interpersonal relationships [2].

There are many classifications of coping mechanisms because these psychological processes are numerous and quite diverse, therefore different authors group them according to more or less arbitrary criteria [9-15]. One example of such a classification has as its core criterion the targeted stressor(s), and includes (1) reactive coping – the individual responds to a certain stress factor; people who activate this type of coping have presumably better adaptive skills in an unstable environment with many hard-to-predict stressors; (2) proactive coping – the individual activates behaviors/thoughts aimed at neutralizing the effects of anticipated stressors; people who activate this coping perform better in a stable environment with routine tasks [1,16].

Another classification of coping mechanisms includes (a) problem-focused strategies – address the origin of the discomfort, and these may be manifested as active coping, planning, restrictive coping (not acting prematurely, holding back until a good opportunity to act appears), and inhibition of concurrent activities; (b) emotion-focused strategies – targeting the decrease of negative emotions correlated with the ongoing stressor, e.g., positive reframing, acceptance, recourse to religion, and humor; (c) meaning-based strategies, i.e., extraction and management of the meaning the stressful situation has for an individual in a certain moment; (d) social or support-based strategies, which refer to the ability of stress reduction by seeking emotional or behavioral support from the group to which that person belongs [1,17].

The coping mechanisms mentioned above are „adaptive” processes, but there is also a category of „maladaptive” coping strategies [18]. It is supposed that problematic coping may develop in the early stages of conscious life when individuals have to face overwhelming stressors like maltreatment, abuse, or neglect [18]. For example, the excessive activation of primitive coping strategies, lack of modeling for healthy coping alternatives, and repeated exposure to intense stressors in the immediate environment are potential factors that may increase the individual's vulnerability to the development of maladaptive coping strategies [18]. These coping mechanisms are associated with a negative evolution of mental health problems and more severe levels of psychopathological manifestations [1]. Examples of maladaptive or dysfunctional coping are represented by disengagement (defined by efforts to move away from the stress triggers), emotional suppression (i.e., inhibition of emotional reactions), cognitive avoidance (manifested by distraction, worry, and thought suppression), and denial (i.e., the unwillingness to accept reality) [19-21].

The role of maladaptive coping mechanisms in psychopathology has been explored intensively, and conditions like posttraumatic stress disorder, anxiety disorders, depressive disorders, psychosomatic disorders, and somatoform disorders have all been correlated with avoidance-based coping or other maladaptive strategies [1]. The situation of treatment or diagnostic refusal in patients with psychiatric disorders, but also in those presenting with different organic illnesses, including cancer, has been associated with maladaptive coping (i.e., denial) [21].

The rationale for exploring coping mechanisms in patients with oncological and other severe diseases is the need to understand better the psychological strategies activated by patients in stressful situations and to work with these strategies during psychotherapy. One aspect of this process is to allow for the formation of a more solid therapeutic relationship, by exploring the adaptive strategies. Other objectives that may involve coping mechanisms are the training of functional coping skills and helping patients to deconstruct the dysfunctional ones.

There is an additional aspect for exploring these mechanisms in patients with cancer, and it refers to the risk of psychiatric comorbidities. As can be anticipated, this diagnosis, as well as the associated treatment and prognosis, may lead to the onset of adjustment disorders, depressive disorders, stress-related pathology, etc. Many authors are highlighting the need for identifying and treating depression in this specific population because this would have a favorable impact on the quality of life and mortality [22-24]. Cases of major depressive disorders (MDD) have frequently been detected in patients with cancer, reaching prevalences of 2-43.5% [22-24]. The importance of coping mechanisms derives from their impact on the evolution of clinical manifestations and therapeutic responses in patients with MDD [25]. A study exploring this impact concluded that maladaptive mechanisms, mainly ruminating, catastrophizing, and self-blaming were the most frequently used by patients with depression [25]. Accepting the current situation, positive refocusing and re-evaluation are functional coping mechanisms, with a protective role in these patients, and these strategies can be used during the psychotherapeutic process [25].

In another study, the importance of coping strategies for resilience was evaluated in patients with panic disorder [26]. The severity of clinical manifestations and maladaptive coping skills decreased during cognitive-behavioral therapy (CBT) administered in a group format [26]. CBT also had beneficial effects on increasing resilience and quality of life in patients with panic disorder, thus highlighting the role of psychotherapy in modulating the influence of coping mechanisms on daily functioning, besides its positive clinical impact [26].

Adjustment disorders illustrate the failure of coping mechanisms' functionality in preserving a safe distance toward stressful stimuli’ negative impact [27]. Also, acute stress reactions and posttraumatic stress disorder are consequences of coping strategies failure, but in these cases, the stressors represent vital threats [27]. Psychotherapy in these cases targets enhancing coping abilities with the specific stressor and increasing the adaptive responses [28]. This is usually done by identifying negative thoughts and replacing them with more adaptive thoughts (i.e., cognitive restructuring), monitoring the experiences aimed at increasing self-efficacy, and behavioral activation [28-30].

FROM CONCEPTUAL ANALYSIS TO CLINICAL SITUATIONS – AN ANALYSIS OF HOW THE COPING MECHANISMS FUNCTION IN SPECIFIC SITUATIONS

As mentioned in the introductory chapter, coping mechanisms are usually activated in stressful situations, and configuring the individual profile of these mechanisms allows the therapist to represent the specific vulnerability features and the resilience factors to stressful situations, like a vital threat raised by a cancer diagnosis. The presentation of several theoretical situations is considered helpful for a better understanding of how the coping mechanisms may work in clinical settings. For example, when a patient finds out that she has been diagnosed with early-stage breast cancer, she may engage in seeking information about this disease and/or making an appointment for further investigations (which implies active, problem-focused coping); also, she may decide to join a self-help group for patients with the same diagnosis (i.e., a coping based on social support), or she may look for spiritual support from a priest (defining a coping based on recourse to religion). However, continuously looking for information that may invalidate the oncological diagnosis, by exploring different online resources, or by repeated medical consultations in the hope of finding a doctor willing to offer another diagnosis, is a maladaptive coping strategy based on denial. In the case of a patient with prostate cancer who has already been investigated by collecting all the necessary laboratory analyses (prostate biopsy included) and by undergoing all imagistic investigations required, the delay of treatment initiation is caused by his lack of trust in the results of these investigations. Due to this maladaptive coping strategy, the treatment initiation is delayed, and the prognosis may worsen.

Another example is represented by a woman with breast cancer who has undergone a total mastectomy and developed a depressive disorder because she refuses to accept her new body image. As a manifestation of her depression, she does not want to consult a mental health specialist, thus activating a coping strategy based on denial and avoidance.

Yet another typical situation is when a person who goes through a divorce caused by health and financial problems ends up consuming alcohol excessively, to suppress his/her negative emotions. This way of facing the specific life situation is characterized by disengagement and avoiding confrontation with own emotions, i.e., two types of maladaptive coping.

On the other end of the coping mechanisms spectrum, a person who has to retire prematurely due to an oncological disease (now in remission, but with several negative functional consequences) may go initially through an adjustment disorder caused by the recent change of the daily activity regime, but then she/he resignifies the situation and considers that she/he has more free time to spend with own family. This is an example of active coping, planning, and coping based on significance because the individual perceives her/himself as a survivor of the disease and focuses on future prospects.

Of particular importance for understanding how coping mechanisms work, is the exploration of the strategies activated and the solutions each patient has found when confronted previously with difficult situations, such as interpersonal conflicts, social isolation, work conflicts, economic difficulties, and severe illnesses [31].

NEUROBIOLOGICAL FOUNDATION OF COPING MECHANISMS AND THE STRUCTURED APPROACH TO THEIR CLINICAL ASSESSMENT

The prefrontal cortex, responsible for executive functioning (i.e., planning, analysis and synthesis, abstracting, problem-solving, verbal fluency, etc.), and the nucleus accumbens, which is part of the reward system or the mesocorticolimbic circuit, have been associated with the functioning of the coping mechanisms [32,33]. These central nervous system (CNS) structures are sensitive to chronic stress, and disruptions in the functioning of the prefrontal cortex have negative consequences on the ability to perform complex cognitive tasks [32,33]. Executive functions, including cognitive flexibility, planning, inhibitory control, error detection, working memory, and verbal fluency, are largely dependent on the morphological integrity and functionality of the prefrontal cortex [34-39]. These functions are essential for constructing coping mechanisms, their preservation or inhibition, and mediating the relationship between coping strategies and different psychiatric disorders, such as MDD [34,35]. It was even demonstrated that interventions targeting the enhancement of executive functions and/or coping mechanisms are useful in decreasing the risk of MDD recurrence [34]. Executive functions have a role in increasing the risk of suicidality by mediating the relationship between high levels of stress and avoidant coping, therefore enhancing executive functioning through computerized training and cognitive rehabilitation may reduce the impact of stressors on individuals [35]. Also, executive dysfunction and mnestic impairments were associated with lower use of active coping mechanisms in patients with schizophrenia, highlighting the important correlations existing between these variables [39].

The activity of the hypothalamic-pituitary-adrenocortical axis (HPAA) and the plasma level of cortisol have no confirmed direct effect on coping mechanisms, but they may influence intermediate variables with impact on, or associated with, these mechanisms [33,40,41]. Such mediators are depressive mood, anxiety, insomnia, psychomotor restlessness, and attentional and memory deficits [33,40,41]. For example, in a study (N=30 participants), the presence of MDD was correlated with a higher level of morning serum cortisol vs. healthy individuals, and an inverse correlation between these levels and the frequency of activated prosocial coping mechanisms was observed [42].

Serotonergic and dopaminergic pathways in the CNS are responsible for modulating mood, strengthening/decreasing certain behaviors, and influencing memory and attention [43-48]. The prefrontal cortex, hippocampus, and corpus striatum, which are involved in cognition, are densely populated by dopaminergic and serotonergic neurons originating within the raphe complex, mesocortical, and nigrostriatal systems [43,49]. Processes like learning and memory depend on the modulation of serotonergic and dopaminergic activity and imply short- and long-lasting synaptic modifications [43]. Modulation of serotonergic and dopaminergic pathways using pharmacological agents, as is the case with MDD and schizophrenia spectrum disorders, can influence not only the core clinical symptoms of these disorders but, indirectly, may modulate the coping mechanisms [50-53].

The impact of vasopressin and oxytocin on psychological mechanisms that are important for the modulation of coping strategies was also explored [54,55]. These pituitary neuropeptides are responsible for shaping social behavior, aggression, and social memory, according to preclinical studies [54,55].

Data about the importance of vasopressin and oxytocin in humans also emerged recently, and functional neuroimaging studies showed that impaired operation of these neuropeptides appears in mental disorders that imply an early attachment disruption or difficulties in forming social relationships, such as autism spectrum disorders (ASD), social anxiety disorder, borderline personality disorder, and schizophrenia spectrum disorders (SSD) [55].

In conclusion, the biological foundation of cognition is extremely complex, and the adequate functioning of the cognitive processes (as a prerequisite for the operational coping mechanisms) depends heavily on the integrity of multiple neurotransmission and neurohormonal pathways.

The assessment of coping mechanisms is conducted by mental health specialists trained in using validated instruments. Besides the general evaluation, based on a psychological interview targeting current mental status and personal history, the specialists may use various scales, inventories, and questionnaires constructed and validated for this purpose.

Brief-COPE is a 28-item, self-administered instrument that quantifies functional and dysfunctional coping methods in stressful situations [56]. It is often used in clinical settings to assess how patients cope with stressors such as cancer diagnosis, heart failure, trauma, and mental and behavioral disorders [56]. Based on interpreting this questionnaire's results, psychological counseling strategies may be formulated [56]. Brief-COPE evaluates three types of coping: (1) problem-focused – includes the following dimensions: active coping, planning, suppression of competing activities, restraint coping, and seeking instrumental social support; a high score indicates coping strategies aimed at changing stressful situations, psychological stability, a pragmatic approach and is a positive prognostic factor; (2) focused on emotions – includes seeking social support, positive reinterpretation, acceptance, denial, and appeal to religion; high scores indicate strategies aimed at regulating stress-related emotions; (3) avoidant – includees emotional venting, behavioral disengagement, mental disengagement; a high score suggests physical or cognitive disengagement efforts, low scores suggest adaptive coping [56-61]. The original COPE inventory included 15 dimensions, each with 4 items [57,62]. However, this form was criticized because the number of factors differed across studies, varying from 3 to 5, it was considered too long, and the distinction between its dimensions was not supported by further analyses [57].

The most frequently used tools for evaluating coping mechanisms, besides the COPE and Brief-COPE, according to a meta-analysis, are the Ways of Coping Questionnaire, Coping Strategies Questionnaire, Coping Response Inventory, Coping Strategies Inventory, Adolescent Coping Scale, Pain Coping Questionnaire, Religious COPE, and Utrecht Coping List [63]. The same source mentioned that coping scales are often used for the structured assessment of patients with various health problems, such as illnesses, pain, and medical diagnoses [63].

COPING MECHANISMS IN PATIENTS WITH ONCOLOGIC DISEASES

Coping mechanisms influence the decision-making process regarding participation in treatment and implicitly shape the evolution and prognosis of the condition. The same mechanisms impact the patient's desire to be informed about their own illness, their perception of self-efficacy, their relationship with others during the illness, etc. The main coping mechanisms identified in a study (N=603 patients with cancer) were (1) seeking or using social support, (2) focusing on the positive aspects of life, (3) distancing, (4) cognitive avoidance/cognitive abandonment, and (5) behavioral avoidance/behavioral abandonment [64]. This study concluded that the type of oncological disease, the time elapsed since the diagnosis of the disease, and the presence of treatment correlated non-significantly with the type of coping [64]. The stress perception associated with the oncological condition correlated significantly with the activation of coping based on social support, but also with cognitive and behavioral disengagement [64]. Coping based on social support, focusing on the positive, and distancing were all associated with less emotional distress, while cognitive/behavioral withdrawal was associated with more emotional distress [64].

The relationship between coping strategies, quality of life, and mood in patients with incurable oncological conditions was investigated in a randomized trial of palliative care, that enrolled patients with advanced stages of lung or gastrointestinal cancer (N=350), who were in the first 8 weeks after the diagnosis was confirmed [65]. All main outcomes were assessed in a structured way, and the most frequently detected coping mechanism was emotional support (77%), followed by acceptance (49%), self-blame (38%), and denial (28%) [65]. Coping based on emotional support was significantly associated with better quality of life and less severe depressed mood [65]. In the same study, acceptance correlated significantly with better quality of life and inversely with depression and anxiety, denial and self-blame correlated significantly inversely with quality of life and non-significantly with depression and anxiety [65]. The study's authors concluded that interventions aimed at improving the quality of life and mood of these patients should include increasing the use of adaptive coping strategies [65]. It also may be stated that patients with incurable forms employ different coping mechanisms than those with oncological conditions presenting a favorable prognosis [65]. The explanation is that the emotional burden and severity of physical symptoms create a different setting for activating coping mechanisms in the two population subgroups [65].

Types of coping activated by patients with breast cancer predict long-term psychological adjustment, according to the results of a study that explored the strategies for facing difficulties related to this diagnosis in a group of 55 patients [66]. Coping mechanisms, decisional control, expression of frustration, and psychological adaptation in the first 6 months after finding out the diagnosis were assessed initially and after 3 years [66]. Patients who were initially depressed and who responded to finding out the diagnosis with cognitive avoidance (acceptance/resignation) showed significantly less chance of psychological adjustment 3 years later [66]. The poor psychological adjustment was significantly associated with cognitive avoidance and minimal activation of proximity/ contact-based coping [66].

The relationship between quality of life and coping mechanisms was evaluated in women extensively treated for advanced-stage genital cancer (N=64) [67]. A control group included women with genital cancer in the early stages, who consequently received less aggressive treatment [67]. The main stressors in the study group were the adverse effects of chemotherapy, poor physical condition, and poor prognosis [67]. Using the COPE inventory to assess coping mechanisms, it was observed that avoidance and engagement were the dominant strategies in patients with severe forms of cancer [67]. Also, these patients presented more frequently both types of coping (commitment/avoidance) vs. patients in the control group [67]. Avoidant coping strategies correlated with more negative mood and poorer overall well-being, while avoidance and seeking instrumental support were associated with worse prognosis in patients with severe forms of cancer, but not in those with early forms [67]. Thus, coping mechanisms have a stronger impact on prognosis in patients with severe forms of genital cancer [67]. Avoidant coping strategies in particular may adversely affect the quality of life and mood in this population [67].

The predictive value of coping mechanisms in patients who were diagnosed with stage I or II breast cancer no more than 12 months ago was the objective of a longitudinal study that included 70 patients [68]. This study explored the abilities of these patients to activate situational-specific coping mechanisms and hope (considered a more stable factor), as predictors of adaptation after finding out their diagnosis [68]. Active acceptance-based coping at the moment of diagnosis predicted better adjustment over time in this population, while avoidance-based coping correlated with greater fear of cancer recurrence, independent of the patient's initial medical condition and age [68]. Religion-based coping proved more effective for women who had a lower initial level of hope [68]. The conclusion of the study was that protective and risk factors for adaptation in first-year breast cancer survivors can be identified even before surgery [68]. Mood characteristics, such as hope, as well as situation-specific coping strategies, must be considered by the case manager [68].

Optimism was explored as a variable mediated by coping strategies in patients with breast cancer in the early stages, in a study with 59 participants [69]. The level of optimism was determined one day before surgery, 10 days after it, and 3-, 6-, and 12 months post-surgery [69]. Acceptance-based coping, positive reframing, and religion were the most frequently activated strategies, and optimism correlated inversely with the level of distress at each of the study visits [69]. Denial and behavioral disengagement were the least frequently activated coping strategies in this population [69]. In conclusion, optimism and pessimism are mediated by the activation of different coping mechanisms in the adaptive process and they have an important role in favoring or hindering this process [69].

The correlation between coping strategies and psychological distress was investigated in patients with advanced stages of cancer [70]. In such a study, that enrolled 132 patients diagnosed with breast, ovarian, lung, colorectal, and other types of cancer, a correlation between distancing, cognitive avoidance, and behavioral abandonment, on the one hand, and psychological distress, on the other, was demonstrated [70]. Distancing coping correlated negatively with psychological distress, while cognitive and behavioral avoidance correlated positively with the same distress [70]. Overall, coping methods explained 36% of the variation in the level of psychological distress [70]. The most important coping mechanism contributing to psychological distress was behavioral avoidance, followed by cognitive avoidance [70].

Emotional expressive coping has predictive value for physical and mental adjustment to breast cancer diagnosis, according to a prospective, 3-month study (N=92 participants) [71]. Active processing of emotions is a coping mechanism based on promoting emotional contact, that favors adaptation and health status [71]. Women who reported emotional expression-type of coping had fewer visits to the doctor for cancer-related symptoms, had better physical health and energy levels, and had lower levels of distress over the next 3 months compared to patients who had less emotional expression [71]. Quality of life was also better in patients with emotionally expressive coping [71].

MDD, personality disorders, and coping strategies were studied as moderators of the quality of life in patients with non-metastatic breast cancer [72]. A cross-sectional study included 120 patients diagnosed with breast cancer 7 months ago, and the main outcomes were quality of life, coping strategies, biological and physiological variables, presence of MDD and personality disorders, and pain severity [72]. Poorer physical quality of life was associated with MDD, younger age, more severe initial tumor stage, and behavioral disengagement coping [72]. A lower emotional quality of life was associated with MDD, the presence of a personality disorder, more severe pain, a high level of self-blame, and a lower use of acceptance-based coping [72]. Also, lower global quality of life was associated with MDD, the presence of a personality disorder, more intense pain, high levels of self-blame, less use of reframing coping strategies, and the absence of hormone therapy [72]. In conclusion, lower quality of life was associated with premorbid patient characteristics (personality disorder) and coping variables (depression, personality, and specific strategies), less so with cancer-related variables (type of treatment, disease severity) [72].

TRAINING OF THE COPING MECHANISMS IN ONCOLOGICAL PATIENTS

Psychotherapy and psychological counseling in patients diagnosed with severe organic illnesses have, between their objectives, the enhancement of functional coping mechanisms and the reduction of maladaptive ones, in order to enhance resilience to stressful situations (e.g., pain, invalidity, changes in lifestyle, adverse events of drugs). Coping skills training programs have been associated with improving some biological and psychosocial parameters in patients with chronic somatic conditions [73]. For example, a decrease in HbA1c levels and an increase in self-efficacy have been observed in patients with diabetes after applying a coping skills training program [73]. The same programs led to increased self-care capacity in diabetic patients, decreased the severity of depressive symptoms, improved the prognosis of chronic obstructive pulmonary disease (COPD), and ameliorated the quality of life in individuals with various somatic conditions [73]. The training of these skills involves lectures, Q&A sessions, group discussions, role-plays, etc., under the direction of a clinical psychologist/psychotherapist; nurses trained for this purpose can also lead such support groups [73]. The topics addressed are the principles of effective self-care, stress management, communication skills training, cognitive-behavioral restructuring techniques, and problem-solving techniques [73].

A brief coping skills training program for oncology patients was designed to increase the patient’s feelings of self-efficacy, personal control, and resilience to stress [74]. Applied in the perioperative framework, this program was created for nurses, and they were trained on how to enhance the patient’s trust in their own abilities to manage dysfunctional cognitions and behaviors [74]. This training was used to prepare the patients for solving situations or events that may occur before or after surgery [74]. Providing information, education, emotional support, and specific interventions – adapted to the objectives of each individual case, were part of this brief training [74]. Relaxation based on breathing, cognitive restructuring, mindfulness, goal setting, and motivational interviewing may be part of more comprehensive training [74].

Encouraging caregivers of oncology patients to participate in the training of coping mechanisms is considered an important aspect of case management. A study that included 233 patients with lung cancer and their relatives compared two interventions – 14 telephone sessions of coping skills training assisted by a relative vs. education/support with the help of a relative [75]. Patients in both groups showed improvements in anxiety and self-efficacy during the 4-month follow-up [75]. However, family-assisted coping skills training has been associated with better outcomes in patients with stage II or III cancer [75]. Caregiver-assisted education/psychological support was more effective in patients with stage I lung cancer [75].

The effects of coping skills training on caregivers of oncological patients were also explored. Such a study enrolled 70 participants and looked at the effects of coping skills training on the quality of life in daughters of patients with breast cancer [76]. The intervention consisted of an educational program, with workshop-type lectures, followed by group discussions [76]. Relatives' quality of life was considerably improved by this intervention, according to Pediatric Quality of Life Inventory scores [76]. Physical, and emotional functioning and participation in school activities were improved vs. the control group [76].

Particular aspects of adaptive strategies training depend on the specific elements of oncological conditions. The approach in a psychotherapeutic setting to patients with cancer must include the training of coping skills, depending on the particularities of each case. It is essential for the therapist to work with the patient in identifying the stress factors that activate coping mechanisms: self-image changing (e.g. mastectomy, limb amputation), reduced mobility, adverse effects of chemotherapy and radiotherapy (e.g. alopecia, persistent vomiting, swallowing disorders, sexual dysfunctions), lifestyle changes (eg, colostomy, indwelling urinary catheter), physical pain, psychiatric symptoms/ disorders – depression, anxiety, restlessness, insomnia, apathy, anhedonia, etc.

Therapeutic interventions may be focused on the activation of functional coping mechanisms, based on action and social support, e.g. looking for a support group for patients who have undergone similar surgical interventions; planning activities based on the spared skills; analyzing the pros and cons of correcting deficits (prosthetics, plastic surgery); re-signification of the situation, e.g. post-operative scars are an indicator of the battle with the disease and of the fact that the person has overcome it, assuming the state of "survivor" or "victor"; creating an optimal framework for expressing emotions, concerns, fears related to the new situation in which the person finds him/herself, dysfunctions of the social image, self-image, and relationships with those close to the patient, decreased professional functioning, etc.; encouraging acceptance of the present situation and redirecting resources towards functional, healthy aspects of own life; acceptance does not mean resignation; adding non-pharmacological methods to drug pain therapy – mindfulness, progressive muscle relaxation, diaphragmatic breathing, guided imagery, planning hobby activities; specific techniques for augmenting the effect of medication in depressive, anxiety, adaptation disorders, insomnia, etc., e.g., cognitive restructuring in depression and anxiety, aversive therapy or relaxation techniques in insomnia, guided imagery and activity planning for isolated affective/anxiety symptoms, etc.

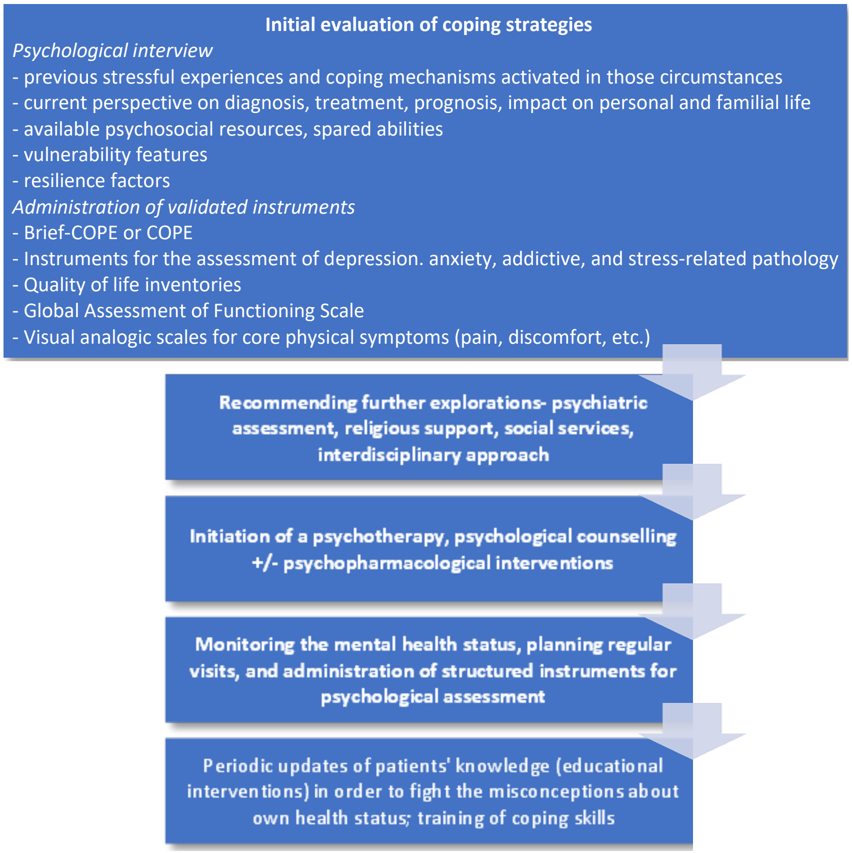
CONCLUSIONS

Coping mechanisms in patients diagnosed with oncological diseases have an important role in preserving mental health, quality of life, and general functionality. Coping mechanisms modulate the vulnerability towards mood and anxiety disorders in patients diagnosed with cancer, but these mechanisms also have an impact on therapeutic adherence, thus representing important factors that correlate with prognosis. The best-defined functional coping strategies are those centered on realistic assessment, problem-solving, emotion-expression, and occupational activation, therefore it is recommended that the therapist train these healthy mechanisms in patients with severe organic diseases.

Coping resources activated in stressful life circumstances include the participation of family or friends, recourse to religious rituals, at least partial maintenance of professional roles whenever possible, and self-help therapy (online sessions, organized groups, etc.).

In oncology patients, maladaptive coping strategies can also be identified, for example, withdrawal from reality, including complete or partial denial of the disease, substance abuse, behavioral addictions, treatment refusal, requesting the administration of insufficiently validated treatments not recommended by a specialist, etc.

The psychotherapeutic approach to patients with cancer should include an initial assessment of coping strategies used both now and in the past under stressful conditions, an evaluation of the psychosocial resources that patients have previously activated in life-threatening situations, and a screening for mood, stress-related, and anxiety disorders that may have been triggered since the onset of the current illness (Figure 1).



Initial evaluation of coping strategies
Psychological interview
- previous stressful experiences and coping mechanisms activated in those circumstances
- current perspective on diagnosis, treatment, prognosis, impact on personal and familial life
- available psychosocial resources, spared abilities
- vulnerability features
- resilience factors
Administration of validated instruments
- Brief-COPE or COPE
- Instruments for the assessment of depression. anxiety, addictive, and stress-related pathology
- Quality of life inventories
- Global Assessment of Functioning Scale
- Visual analogic scales for core physical symptoms (pain, discomfort, etc.)
Recommending further explorations- psychiatric assessment, religious support, social services, interdisciplinary approach
Initiation of a psychotherapy, psychological counselling +/- psychopharmacological interventions
Monitoring the mental health status, planning regular visits, and administration of structured instruments for psychological assessment
Periodic updates of patients' knowledge (educational interventions) in order to fight the misconceptions about own health status; training of coping skills

Figure 1: The algorithm for assessing and training coping mechanisms in patients with cancer

After this stage, a psychiatric consultation may be recommended, if necessary (acute psychiatric pathology, the need for pharmacological treatment). The initiation of psychological counseling, psychotherapy, and, in specific cases, psychopharmacological treatment may be prescribed, depending on the results of the initial evaluation. Monitoring the mental health status by using standardized tools, and planning follow-up visits to update patients' knowledge and coping skills learned is necessary. The psychotherapeutic intervention should be focused on increasing adaptive coping through systematic training and highlighting the disadvantages of dysfunctional coping mechanisms. This therapeutic process can have a significant favorable impact on treatment adherence, mental health status, and quality of life in patients with cancer

Further research on this topic should investigate the impact of structured coping skills training programs on more homogenous populations, such as patients with a certain type of oncological disease and in a specified stage of the disease's evolution [77-79]. Of major interest would be the exploration of combined therapeutic interventions in this population, and also the assessment of the impact different types of surgical interventions may have on mental health and quality of life [77-83]. As a limitation of this review, it should be mentioned that it was not designed as a systematic approach to this topic, its immediate purpose is to enhance the awareness of mental health specialists about the importance of assessing and addressing during therapy the important aspect of coping strategies.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research received no external funding.

Authors' contribution

OV conceived the idea of the review. OV, AGM, BMP, CAC, CFP and REBB designed the study. OV, CFP, REBB, AFF, MCP, CAS and CN screened the studies and abstracted the primary sources. OV, AGM, BPM and CAS drafted the first version of the review. OV, CAC, CFP, AFA, MCP and CAS revised the manuscript and elaborated the conclusions of the review. All authors had full access to all data contained in the review and decided to submit the manuscript for publication.

Abstract: *Background and Aim: Health technology assessment for drugs is a necessary step in developing health policies that are focused on patients and getting the best value for scarce resources. One important feature of health technology assessment is transparency. In many countries, health technology assessment is followed by negotiations between pharmaceutical companies and health authorities to determine whether a drug will be publicly funded. These negotiations often result in Managed Entry Agreements, which typically include confidentiality clauses covering the final price of the drug. Methods: We reviewed Romanian legislation starting in 2014 to assess the level of confidentiality and transparency in drug pricing and reimbursement. Results: We found that for drugs with Managed Entry Agreements, the level of discounts is confidential, the public does not know how much the government is paying for each of these drugs, the volumes (units) of drugs are not transparently published by the payer, the outcomes, in terms of patients treated by therapeutic area, therapeutic success, and resource utilization, are confidential. Conclusions: We consider that too much confidentiality can prevent the public from knowing if the government is getting good value for money, but too little confidentiality can lead to higher drug prices or a lack of drugs from the market.*

Keywords: *managed entry agreements, health technology, confidentiality, pricing, reimbursement*

INTRODUCTION

Every year, the pharmaceutical industry introduces new drugs on the market, constantly developing new solutions for known illnesses. The licensing mechanisms of new drugs are already fully regulated, and the beneficial effects and potential risks have been proven through numerous preclinical and clinical studies [1].

One of the main concerns of each country in establishing its policy on medicines is the permanent increase in the price of new medicines, which generates a growing pressure on the budgets allocated to health [2]. Once they enter the market, the big challenge for a new drug is to be accepted for financing from public funds (or through the health care mechanisms specific to each country). For this, in most of the EU countries, each drug is passed through the very fine sieve of the Health Technology Assessment (HTA) process, the ultimate goal of which is to provide health decision-makers with sufficient relevant information based on which to establish priorities in the field of care, such as the reasonable cost that they afford, and the level of financing, their efficiency, respect for legal and ethical values, and equity.

To develop patient-focused health policies that seek to achieve the best value for scarce resources, one characteristic of the HTA is the transparency of the process [3]. Together or after the HTA process, in numerous countries, there is a practice of negotiations between the Marketing Authorization Holder (MAH) and health authorities to get access to a drug to public financing using Managed Entry Agreements (MEA). In 1993, first-time conventions, lately called MEAs, were introduced between producers and third-party payers, targeting discounts and rebates for innovative drugs [4,5].

The need for these contracts was born from the producers' desire to make price reductions only in the conditions in which they obtain guarantees regarding the avoidance of parallel import and the downward spiral of the price as a result of the fact that the visible price decrease in one country attracts a decrease in all other countries and finally even in the respective country as a result of the use of reference prices. From this perspective, MEAs have a common denominator, respectively, the confidentiality covering the final price of the drug generally as a means to avoid price decreases in other countries.

On the other hand, the third-party payer is interested in keeping costs within a predictable and bearable margin, obtaining superior outcomes for patients, and spending the available resources as efficiently as possible [4]. MEAs can be divided into financial agreements that directly affect the budget (confidential discount or rebate, price-volume agreements, volume or expenditure cap, free initial treatment, etc.) and performance-based agreements that evaluate the treatment's performance (coverage with evidence development, payment by result, conditional treatment continuation, etc.) [4,6,7].

In Romania, a scorecard model called HTA was introduced in 2014. This is based primarily on the results of the assessments or reimbursement status for the respective drugs in EU countries. The health authorities decided in 2015 to increase the financial sustainability of the new drugs through the transfer of financial risk to MAHs via Managed Entry Agreements (known locally as Cost-Volume contracts, which are financial-based agreements, and Cost-Volume-Results contracts, which are performance-based agreements) [8]. The introduction of MEAs allowed a thawing of the introduction of innovative products on the reimbursement list for medicine (the List), after many years of impasse.

To conclude a functional MEA for a drug, there are several mandatory steps in Romania, some of which are confidential and some of which are transparent. These steps are (1) publishing of the List prices in the Official Gazette; (2) submitting the HTA dossier, obtaining the HTA body's approval and publishing the HTA Report; (3) negotiating the MEA, if applicable; and (4) adding the drug on the List.

METHODS

We performed a critical review of the Romanian legislation and rules, from the last 10 years, looking for the confidentiality and transparency aspects covering the pricing and reimbursement of drugs with MEA.

In our research, we worked to identify the elements of the lack of transparency in the price negotiation process for medicines or related to it that could lead to a discrepancy between the benefits offered to patients and the actual price paid.

RESULTS

The Romanian regulations do not stipulate the confidentiality of the final purchase prices. The joint order from the Minister of Health and the President of the National Health Insurance House (NHIH) requires that any confidential information obtained during the execution of the MEA contract (Cost-Volume contract) be used only to fulfill the MEA's purpose and not be disclosed or utilized for other reasons, including the final price of the medication in question [9].

Our analysis revealed that drug reimbursement in Romania through MEAs involves a blend of public and confidential data.

In Romania, there are two List Price catalogs: (1) one used for public reimbursement (Canamed) [10] and (2) one used only by pharmacies or health care providers not having a public reimbursement (Public Catalogue) [11]. Both catalogs are publicly available in the Official Gazette and on the Ministry of Health website [12], while Canamed can be seen also with the reimbursement price on the local payer website [13] (last update on July 1st, 2021). For the International Reference Pricing process done by other countries, the Ministry of Health recommends the use of the Public Catalogue (with higher List prices than Canamed).

The submission of the HTA dossier is a highly confidential process, with most of the steps not transparent: the content of the HTA dossier, the members of the evaluation team from the HTA body, the deadline for the evaluation, and the involvement or not of the Specialty Commissions from the Ministry of Health. Every month, the HTA body (National Agency for Drugs and Medical Devices – ANMDM) publishes a list of the drugs received for HTA evaluation. Next, the HTA report for each drug and the decision and the meeting minutes of the Appeal Committee (only for the drugs where the MAH was not satisfied with the results of the HTA report) are also published.

The HTA methodology allows the MAH to offer (part of the HTA dossier) a "confidential discount" to the payer (NHIH), one key aspect of confidentiality, resulting in a lower price compared to its competitor. This "confidential discount" should be part of a Protocol between MAH and the payer to include the obligation of the MAH to lower the net price (not visible) once the HTA report is positive and then the drug is included in the Reimbursement List 2020 [14].

The negotiation of a MEA is mainly a confidential process. The decision to apply for an MEA relies on the MAH level and also the proposal to be addressed to the Negotiation Committee. The negotiation is contingent upon the number of patients under contract and the eligible population. Ministry of Health (MoH) Specialty Commissions establish the eligible population and publish it on the payer website. Often, these Commissions are not transparent about the data they use to define and establish the eligible population. The number of contracted patients is strictly confidential because the ratio of contracted patients to eligible patients determines the discounts to be paid by MAH as part of MEA (between 25-75%). The table with these discounts is publicly available and published in the Official Gazette (Table 1) [9,15]. This section may be divided by subheadings. It should provide a concise and precise description of the experimental results, their interpretation, as well as the experimental conclusions that can be drawn.

Table 1: Discounts for MEA depending on the market share covered

Percent (%) applied to quarterly consumption (single drug)	Percent (%) applied to quarterly consumption (multiple winners for substitutable drugs)	Percent (%) no. of contracted patients from the no. of total eligible patients
25%	30%	<5%
30%	35%	5-15%
35%	40%	15-25%
40%	45%	25-35%
45%	50%	35-45%
50%	55%	45-55%
55%	60%	55-65%
60%	65%	65-75%
70%	75%	>=75%

The term for these MEAs is one year and is publicly available, their starting point is the first month after the inclusion of the drug in the List.

The renegotiation process involves a simpler approach, with a publication of the moment for negotiation and a clear request for the Specialty Commissions to provide arguments regarding the change in the eligible population.

Other optional aspects of the negotiation, like the coverage by the MAH of some testing or other services, are usually available to the public on the websites of the local affiliates of the payer, due to the need to inform the providers of these aspects [9].

After the conclusion and the execution of the MEA, the MAH will pay the final discount to the payer according to the effective patient share, irrespective of the contracted patient share and discount. The respective data is provided by the payer only to the MAH and nobody else could access this information.

The Parliament approves the payer budget for MEA negotiation and contracting through the State Budget Law. The process of determining this MEA budget is not transparent to the public [16]. Meanwhile, the payer discloses the remaining budget after every round of MEA negotiations. The payer typically reserves a certain amount of its drug budget for drugs that require a new yearly MEA contract to ensure the continued operation of existing MEAs. If the contracting budget is over, no new MEA is signed and for the existing MEAs, there is no renegotiation; only the included patients can continue their treatment and there are no new inclusions of patients.

The budget for drugs with MEA is not available to the public on a monthly or quarterly basis, but at the end of each year, the authorities issue a note detailing the total budget used. MEA's budget information is also included in the Payer Yearly Report, published in the second half of the following year.

The decision to include the drug on the List is highly political, as it requires budget allocation for its introduction. The process for the calculation of budget needs for new drugs is not transparent. The information is only publicly available once the draft of the List is published for public comment.

DISCUSSION

Some authors have pointed out that the classically invoked reasons, namely that the prices of new drugs are very high because most of the income is reinvested in research, are no longer in line with the reality of the time. Drug manufacturers often carry out a series of additional purely financial operations, such as mergers and acquisitions and stock transactions, and play an active role in the capital market, etc. [9,17]. In recent years, concern has grown regarding the confidentiality of the final purchase prices of medicines; in 2019 WHO recommended to member states that they take measures in this regard [18].

The MEA process's opacity creates advantages and disadvantages for the MAH and NHIH regarding the confidentiality of final prices paid by the public payers. The opaque process of setting new budgets extends also for the case when MEAs and the random addition of expenses every time a new product is conditionally approved creates confusion among drug beneficiaries and competing MAHs. Other beneficiaries of the health-care system who require additional funds (except for new drugs) frequently raise concerns.

The legislation for the MEA budget grants access to new drugs on a first-come, first-served basis. Priority criteria are also considered and include the unmet need, the drugs with EU emergency approval, and the public health reasons [15].

The payer does not transparently publish the volume (units) of drugs, including those with MEAs. The only publicly available data on the payer's website is at the ATC3 level and the INN level for the top 10 drugs in terms of value reimbursed in open pharmacies for each category (A, B, C, D, and E) of the reimbursement List [19]. Contract monitoring is challenging because currently there is no way to access treatment outcome data or resource utilization for patients receiving MEA treatments; the payer does not conduct cost-effectiveness analyses or publish data; and manufacturers do not have access to confidential patient outcomes.

The confidentiality stipulated in the MEA prevents not only price comparisons but also the comparisons of the treatment outcomes, making it impossible for any researcher to develop any pharmacoeconomic analysis or to monitor the physician's performance.

There are no transparent rules on the term to publish the updated List (and include the newly evaluated drugs), as the legislation only specifies an update once a year. The practice has shown that shorter terms are needed.

The payer agrees to keep the final prices confidential to avoid the risk of the producer choosing not to sell in Romania than to affect the prices in other countries and decrease the access to new technologies for the population, which would be discriminatory.

The confidentiality of the final price could also be viewed as means to respond to limited resources available in the healthcare sector and is linked with delayed access to innovative technology which could address also the quality of care and patient safety, but even with more resources these aspects will be removed only through a better understanding from the health care professionals [20].

Before 2017, payers and manufacturers would sign collaboration protocols, which included confidential discounts. Protocols aimed to decrease prices in Romania's public healthcare system without affecting the visible drug price or international reference price. Due to unclear legislation, these protocols were abolished and replaced with a new type of protocol where the MAH could support some of the financing burden of the payer [21].

The Payer determines the reimbursement prices (reference price) based on a specific methodology, but its application is not transparent [22]. Anyone can find prices on NHIH's website, and pharmacies will charge co-payments if drug prices are higher than the reimbursement price.

As other authors have already pointed out, the various confidentiality elements of the MAH process prevent other possible cost-containment policies from being used. Meanwhile, in Romania, some of these policies are also used (biosimilars/generic stimulation for prescription, reference pricing, protocols and guidelines for prescriptions, some open tenders for exclusivity) while others are waiting to be implemented (price ceilings, value-based pricing, pay for performance, etc.) [23]

Looking at the future development of MEA in Romania, there are plans to expand from simple cost-volume contracts to other types of MEA, including the payment for performance mechanisms. For this aspect, there will be a need for merging patient-level data with drug-patient data, yet not generally available in Romania at the health system level, but only in some of the hospitals, and the definition and the confidentiality of these patient outcomes will be a new issue during the implementation [24,25].

The future of MEA in Romania will be linked with the new EU Directive on HTA, which will become effective in 2025, and some local projects funded by the MOH in regarding pricing, reimbursement, and HTA. The utilization of a classic HTA model with cost-effectiveness in place could replace the actual scorecard HTA model. This will create the case for the confidentiality of prices used in the cost-effectiveness analysis but will benefit from the public availability of outcomes measures like the local values for Quality Adjusted Life Years (QALY) and will catalyze the efforts to determine the cost of QALY in Romania [26,27,28].

CONCLUSIONS

The negotiation process for the MEA in Romania results in a confidential final price, making it difficult to compare with other EU countries.

Confidential price rises question the legitimacy of some decisions and, in particular, the impossibility of checking over time the cost-effectiveness of drugs in the absence of the knowledge of the cost effectively paid. The solution is finding proper ways to provide more transparency in the process, especially regarding budget allocation. This can be obtained using guidelines as a result of cooperation between all interested actors.

From this perspective, the entire process of delivering drugs to the public domain is a new paradigm that requires new means of increasing the equity of financial allocations within the healthcare system while ensuring profitability for the MAH and accessibility for the patients. The key solution is better collaboration and communication between stakeholders keeping in mind to meet patients' needs and expectations.

Sentinel Node Biopsy Positivity: Is Axillary Dissection Always Necessary? – A Retrospective Analysis

Abstract: *Breast cancer remains a significant health concern, with predictions indicating a rise in global incidence. While the primary focus is on oncological radicality, the aesthetic and psychological impacts of surgical interventions, such as radical mastectomy, cannot be ignored. This study, conducted over 8 years, aimed to identify factors that can prevent unnecessary lymphadenectomy. The research analyzed various parameters, including age, BMI, tumor size, and immunohistochemistry, to determine their correlation with axillary lymph node invasion. The results highlighted the importance of tumor size and estrogen receptor status in predicting axillary lymph node metastasis. The study underscores the value of sentinel lymph node biopsy in early breast cancer treatment, emphasizing its benefits over complete axillary lymph node dissection.*

Keywords: *breast cancer, lymphadenectomy, sentinel node biopsy*

INTRODUCTION

According to the American Cancer Society, one out of eight women in the United States will develop breast cancer during their lifetime [1]. Predictions regarding the global incidence of breast cancer in women outline the idea that the incidence will reach approximately 3.2 million new cases per year by 2050.

These numbers reflect the magnitude of breast cancer incidence, its impact on women worldwide, and the ongoing and urgent need to take measures towards prevention and proper therapeutic management [2].

The goal of oncological radicality remains essential and obligatory, but breast neoplasm surgery must also consider the aesthetic component due to the psychological impact that a major surgical intervention, such as radical mastectomy, has on patients. In the early stages, breast cancer can be treated without such a procedure being necessary.

Therefore, in today's times, the gold standard of breast cancer surgery is represented by conservative treatment. It involves the resection of the primary tumor with oncological safe margins and sentinel lymph node biopsy, followed by adjuvant radiotherapy [2,3].

The surgical management of the axilla has always been a controversial topic. For a very long time, it was believed that achieving good loco-regional control involves a complete axillary lymph node dissection, with this method being the gold standard of that era.

In recent years, due to the observed increase in morbidity and decrease in the quality of life for these patients, the method has been abandoned and replaced by sentinel lymph node biopsy.

The technique of identifying the sentinel lymph node (SLN) is based on the theory of the lymphatic spread of cancers, with the neoplastic invasion occurring in a lymph node that drains lymph from the site of the tumor [4,5] .

The prime objective of this study is the identification of factors that can prevent unnecessary lymphadenectomy.

MATERIALS AND METHODS

Based on the purpose and objectives of the research, the research design and methodology have been defined, with its main characteristics being: retrospective - spanning over an 8-year interval - January 1, 2014 - December 31, 2021, single-center, descriptive and correlational, non-interventional.

The eligibility criteria were as follows:
- Diagnosis of breast cancer
- The presence of axillary management after a positive sentinel node biopsy
- Female sex
- Stage IIA-IIIB:
    - o IIA (T2N0M0, T1N1M0)
    - o IIB (T2N1M0, T3N0M0)
    - o IIIA (T3N1M0)
    - o IIIB (T4N1M0)
- Single tumor, excluding multifocal and bilateral cases
- The presence of all required data
- Age > 18 years
- M0
- Any Histopathological type

RESULTS

The working hypothesis considers patients who underwent the sentinel lymph node technique, and the result was positive. In this situation, studies have shown that up to 1/3 of cases present a negative result of the axillary lymphadenectomy. To assess the risk factors for a positive axillar biopsy, we made a comparison between group E – a positive result of axillary lymphadenectomy (34 cases), and group D – a negative result of axillary lymphadenectomy (15 cases) (Table 1).

Table 1: Comparative data of groups (E vs. D)

SNB results	+	+
ALND	✓	✓
ALND results	-	+
Case numbers	15	34

Age

There was no statistical correlation between the age of the patients and the presence of axillary invasion in patients with a positive sentinel lymph node, even though there was a mean difference of 5.85 years - p=0.175 (Table 2 and Figure 1).

Table 2: Comparative statistical data regarding age (E vs. D)

	Age	
	E	D

Bio-clinical analysis

Comparative assessment of routine laboratory test values collected upon admission highlights relatively small differences between the groups discussed in this hypothesis.

The only parameter that demonstrated moderate statistical significance was the white blood cell count - with a mean difference of 1.44 and p=0.065 (Table 4 and Figure 3). Tumor markers did not show statistically significant differences.

Quadrant

The location of the tumor did not correlate with the extent of the axillary invasion, even though there were differences in the distribution of cases concerning this parameter, the statistical significance was not relevant (Tables 5 and 6).

Tumor size

The distribution of tumor sizes highlights higher values within group E - with axillary lymph node invasion, with a mean difference of 8.7 mm and a statistical significance of p=0.04 (Table 7 and Figures 4 and 5).

Immunohistochemistry

From the perspective of evaluating the presence of hormone receptors in the immunohistochemical assessment of breast resection specimens, only estrogen receptors have been identified as a risk factor for axillary invasion beyond the sentinel lymph node. The calculated risk is 7.33 times with a statistical significance of p=0.005 (Tables 8 - 10).

Subtype

From the perspective of molecular subtypes, the division into Luminal A, Luminal B, and Triple Negative did not show a statistically significant correlation with the presence of axillary lymph node invasion in patients with a positive sentinel lymph node. In the case of the HER2 sub-type, the risk of axillary lymph node invasion was nearly 10 times higher - p=0.084 (Tables 11-14).

DISCUSSION

The literature describes four parameters as independent factors of lymph node metastasis, namely lymphovascular invasion, primary tumor size, multiple foci, and tumor localization.

An independent prognostic factor for disease-free survival (DFS) that has been recently analyzed in literature for patients with breast carcinoma is the degree of lymphovascular invasion [6].

Additionally, lymphovascular invasion is associated with a higher frequency of axillary lymph node metastases [7]. To use this data as a tool in determining the indication for sentinel lymph node biopsy (SLNB) or axillary lymphadenectomy, more extensive studies are needed to specifically determine the degree of invasion and the cutoff value that necessitates radical intervention.

A series of studies have demonstrated that younger age is a risk factor for positive axillary lymph nodes (ALN) [8–11]. This has been attributed to more biologically aggressive tumors in this younger age group. The average age of menopause is around 50 years, so most literature establishes 50 years as a cutoff point in exploring the relationship between age and clinicopathological factors in invasive breast cancer [8,12]. The current study did not show correlations between the risk of axillary lymph node spread and age, BMI, and the biological status of breast cancer patients, with results similar to those described in the studies.

Histologic grade and tumor size (often over 5 centimeters in size) are also important predictors of lymph node metastasis. The probability is high if a patient has a large tumor and a high histologic grade. Our presented data show that patients with larger tumor sizes and a high histologic grade are more likely to have axillary invasion, a finding that aligns with those from previous studies [1,6,13–15]. Patients with small invasive breast cancer might benefit from SLNB.

The inclusion of extranodal extension in the evaluation protocol is necessary to achieve precise oncologic staging. Although attempts have been made to establish cut-off values for the circumferential and perpendicular diameters of invasion extension, these have not yielded significant predictive values. Therefore, more extensive studies are needed to specifically determine the dimensions of invasion from which axillary lymph node metastatic burden can be predicted, subsequently guiding the appropriate therapeutic approach [16,17].

Estrogen receptor status was another factor that showed a significant correlation with axillary lymph node involvement, with a calculated risk of axillary invasion beyond the sentinel lymph node being 7.33 times higher in HER+ patients. Various studies have evaluated the role of hormonal receptor status in predicting axillary lymph node metastasis (ALNM) with contradictory results. Capdet et al. [18,19], in their study of 1416 patients with early breast cancer, found no association between hormonal status and lymph node involvement. In contrast, Lee et al. [20] reported a high incidence of ALNM regardless of tumor size in the Korean population with T1-2 breast carcinoma. Finally, in a recent study conducted by Holm-Rasmussen et al. [21], patients with ER-negative tumors had a reduced risk of ALN involvement at the time of diagnosis compared to other patients.

Large integrative analyses are necessary to explain why ER-negative tumors have a low rate of axillary metastases and a high rate of distant metastases. Conversely, HER2-positive tumors have an axillary metastasis rate closely linked to tumor size and a high rate of distant metastases [22,23].

Among the limitations of the study, the retrospective nature of its design, the small number of tracked patients, and the lack of information regarding the use of chemotherapy, radiotherapy, or hormone therapy are identified.

Systemic therapies, including hormonal therapy, cytotoxic chemotherapy, and/or radiation therapy, remain critically important, especially in the treatment of breast cancer with positive lymph nodes [24–28]. Therefore, the results of this study will contribute to decision-making regarding the addition of axillary lymph node dissection (ALND), systemic therapy, and/or radiotherapy in the case of SLN metastases efforts to determine the cost of QALY in Romania [26,27,28].

CONCLUSIONS

Regional lymph node staging is necessary for tumor staging and surgical planning. Previous studies have identified several important factors in predicting axillary lymph node metastasis (ALNM), but the predictive power has not been satisfactory.

With advancements in surgical techniques, sentinel lymph node biopsy (SLNB) is now widely used in early breast cancer and has become a standard procedure in clinically node-negative patients. The benefits of SLNB include fewer surgical complications than complete axillary lymph node dissection (ALND) and effectiveness and accuracy in long-term follow-up.

Abstract: *Psoriasis has been associated with metabolic syndrome and nonalcoholic fatty liver disease. We wanted to investigate the abdominal ultrasonography results of psoriasis patients before biological agent treatment. Between April 2019 and February 2022, abdominal ultrasonography results of psoriasis patients which were performed before biological agent treatment were reviewed retrospectively. This study included 90 patients, 45 females, and 45 males with a mean age of 48.91±13.43 years. The most common ultrasonography finding was increased echogenicity of the liver parenchyma due to steatosis (58.9%) which was followed by an increase in liver size (25.6%), kidney cysts (17.8%), gallstones (8.9%) and increase in spleen size (7.8%). Hepatic steatosis was more frequent in older patients ($p<0.001$), patients with diabetes ($p=0.007$), and patients who were previously treated with biological agents ($p=0.007$). 70.4% of the patients with moderate or severe hepatic steatosis were female. Herein, hepatic steatosis was detected in 53 (58.9%) patients. Nonalcoholic fatty liver disease which presents as hepatic steatosis in early stages has an asymptomatic course and poor prognosis in psoriasis patients. We suggest that abdominal ultrasonography should be performed in psoriasis patients before biological agent treatment, especially in females, patients with advanced age, patients who were previously treated with biological agents, and patients with diabetes.*

Keywords: *abdomen; biological agents; hepatic steatosis; psoriasis; ultrasonography*

INTRODUCTION

Psoriasis is a systemic inflammatory disorder that primarily affects the skin and may present with various comorbidities such as psoriatic arthritis, nonalcoholic fatty liver disease, diabetes, metabolic syndrome, and inflammatory bowel disease [1]. Tumor necrosis factor-α (TNF-α), interleukin-17 (IL-17), and IL-23 are the cytokines mainly responsible for the inflammation in psoriasis [2]. Chronic inflammation has been implicated in the development of accompanying comorbidities. On the other hand, non-alcoholic fatty liver disease which is an important comorbidity of psoriasis due to its risk of progressing to cirrhosis has been associated with the development of severe psoriasis since it may lead to inflammatory cytokine production from the liver [3]. Biological agents affect specific pathways of the immune system that are implicated in the etiopathogenesis of psoriasis. Several biological agents have been developed and successfully used for the treatment of psoriasis. It has been suggested that biological agents were more effective and safer than conventional systemic treatments of psoriasis which lead to a broad immunosuppressive activity [4]. However, some safety concerns have been raised due to the widespread and long-term use of biological agents. Hepatotoxicity, reactivation of hepatitis B and latent tuberculosis infection, exacerbation of inflammatory bowel disease, and invasive fungal infections have been reported in psoriasis patients treated with biological agents. Side effects vary on each biological agent received [5]. For instance, administration of TNF-α inhibitors for long periods may lead to weight gain which has a negative impact on nonalcoholic fatty liver disease in patients with psoriasis [6].

Furthermore, it is controversial whether biological agent treatment increases the risk of malignancy in patients with psoriasis or not. Fiorentino et al. reported that the risk of malignancy might be increased in patients with psoriasis treated with TNF-α inhibitors for longer than a year [7]. On the other hand, Mastorino et al. stated that the use of biological agents affecting TNF-α, IL-17, IL-12, and IL-23 for the treatment of psoriasis was safe even in patients with a past medical history of malignancy [8]. It has been suggested that abdominal ultrasonography might be performed in patients with psoriasis before the initiation of treatment with biological agents to exclude intraabdominal malignancy such as lymphoma and it might be repeated during the treatment [9]. However, abdominal ultrasonography is not included as a pretreatment test to be performed in psoriasis patients before the initiation of biological agents in major guidelines such as Joint American Academy of Dermatology – National Psoriasis Foundation (AAD-NPF) guidelines of care for the management and treatment of psoriasis with biologics and EuroGuiDerm guideline on the systemic treatment of psoriasis vulgaris [10, 11].

Within this study, we aimed to evaluate abdominal ultrasonography results of patients with psoriasis which were performed before the initiation of biological agent treatment**.**

MATERIALS AND METHODS

Gazi University Ethics Committee approval was obtained before this study (approval number: 2022-264). Between April 2019 and February 2022, medical records of patients with psoriasis who underwent abdominal ultrasonography before biological agent treatment were evaluated retrospectively. Psoriasis type, disease duration, psoriasis treatment, accompanying psoriatic arthritis, and systemic diseases were reviewed. All patients with psoriasis aged 18 years and over with complete data have been included in the study.

Statistical analysis was performed using SPSS version 20.0. Quantitative variables were represented as mean ± standard deviation or median and interquartile range, categorical variables were represented as counts and percentages. Kolmogorov-Smirnov test was used to determine whether variables were normally distributed or not. Differences in variables between the two groups were evaluated by chi-square test, independent sample t-test, and Mann-Whitney U test. P values less than 0.05 were considered statistically significant.

RESULTS

This study included 90 patients, 45 females and 45 males. The mean age of the patients was 48.91±13.43 years (range: 19-75 years). 79 (87.8%) patients had psoriasis vulgaris, 8 (8.9%) patients had generalized pustular psoriasis, and 3 (3.3%) patients had palmoplantar psoriasis. The mean disease duration was 19.35±11.93 years (range: 2-53 years). The median Psoriasis Area and Severity Index (PASI) was 7.2 (11.4) [12]. Psoriatic arthritis was detected in 34 (37.8%) patients. 34 (37.8%) patients were treated with ustekinumab, 29 (32.2%) patients were treated with IL-17 inhibitors such as secukinumab and ixekizumab, 23 (25.6%) patients were treated with TNF-α inhibitors such as adalimumab, infliximab and certolizumab pegol, 4 (4.4%) patients were treated with IL-23 inhibitors such as risankizumab and guselkumab. All patients previously received conventional treatments such as acitretin, cyclosporine, and methotrexate. 15 (16.7%) patients were previously treated with phototherapy. 37 (41.1%) patients were previously treated with biological agents whereas 53 (58.9%) patients were biologic-naive. None of the patients stated excessive alcohol consumption. Past medical history was unremarkable in 48 (53.3%) patients. However, 23 (25.6%) patients had hypertension, 17 (18.9%) patients had diabetes, 4 (4.4%) patients had chronic obstructive pulmonary disease, 4 (4.4%) patients had asthma, 4 (4.4%) patients had hypothyroidism, 4 (4.4%) patients had chronic hepatitis B virus infection, 3 (3.3%) patients had chronic kidney disease, 3 (3.3%) patients had coronary artery disease, 1 (1.1%) patient had nephrolithiasis, 1 (1.1%) patient had villous adenoma of the colon. In addition, 1 (1.1%) patient had a history of testicular seminoma, 1 (1.1%) patient had cervical cancer, and 1 (1.1%) patient had urothelial carcinoma.

Abdominal ultrasonography revealed an increase in liver size in 23 (25.6%) patients (the mean craniocaudal length in the midclavicular line: 16.69±0.96 mm, range: 15.5-20 mm). Among the patients with increased liver size, 17 (73.9%) were female and 6 (26.1%) were male (p=0.013). Increased liver size was observed in 14 (60.9%) patients with psoriatic arthritis and in 9 (39.1%) patients without arthritis (p=0.008) (Table 1). Increased liver size was more common in patients with hypertension (10, 43.5%) compared to patients without hypertension (13, 19.4%) (p=0.023). Increased liver size was observed in 6 (35.3%) patients with diabetes and 17 (23.3%) patients without diabetes (p=0.309).

The mean psoriasis duration was 22.15±12.47 years in patients with increased liver size and 18.39±11.68 years in patients with normal liver size (p=0.185). Among the patients with increased liver size, the mean craniocaudal length was 17.03±1.10 mm in those who were biologic-naive and 16.25±0.48 mm in those who received biological agents previously (p=0.037). All patients with increased liver size showed increased echogenicity of the liver parenchyma due to steatosis. An increase in echogenicity of the liver parenchyma due to steatosis was reported in 53 (58.9%) patients [mild: 26 (28.9%), moderate: 14 (15.6%), severe: 13 (14.4%)]. The mean age of the patients with and without increased echogenicity of the liver parenchyma due to steatosis was 53.62±11.71 years and 42.16±12.99 years, respectively (p<0.001).

Table 1: Patients with increased liver size and increased echogenicity of the liver parenchyma

	Increased liver size		**P value**
Patient characteristics (n, %)	Female (17, 73.9)	Male (6, 26.1)	0.013
	With psoriatic arthritis (14, 60.9)	Without psoriatic arthritis (9, 39.1)	0.008
	With hypertension (10, 43.5)	Without hypertension (13, 19.4)	0.023
Craniocaudal length (mm, mean±SD)	Biologic-naïve (17.03±1.10)	Previous biologic (16.25±0.48)	0.037
	Increased echogenicity of the liver parenchyma due to steatosis		
Patient characteristics (n, %)	Previous biologic (28, 75.7)	Biologic-naïve (25, 47.2)	0.007
	With diabetes (15, 88.2)	Without diabetes (38, 52.1)	0.007
Moderate/severe (n, %)	Female (19, 70.4)	Male (8, 29.6)	0.021

SD: Standard deviation. Increased liver size was more common in patients with psoriatic arthritis and hypertension. Moderate or severe increase in the echogenicity of the liver parenchyma due to steatosis was more common in female patients.

Among the patients with increased echogenicity of the liver parenchyma due to steatosis, 28 (75.7%) received biological agents previously and 25 (47.2%) were biologic-naive (p=0.007). Increased echogenicity of the liver parenchyma due to steatosis was detected in 15 (88.2%) patients with diabetes and in 38 (52.1%) patients without diabetes (p=0.007). Among the patients with a moderate or severe increase in the echogenicity of the liver parenchyma due to steatosis, 19 (70.4%) were female and 8 (29.6%) were male (p=0.021). In addition, heterogeneous liver parenchyma was reported in 5 (5.6%) patients, hypoechoic areas in the liver which might be compatible with focal fatty sparing in 4 (4.4%) patients, liver cyst in 3 (3.3%) patients, hyperechoic liver lesions which might be compatible with hemangioma in 3 (3.3%) patients and Chilaiditi syndrome was reported in 1 (1.1%) patient.

Moreover, gallstones were detected in 8 (8.9%) patients (the mean diameter: 15±7.05 mm, range: 3-20 mm) and gallbladder polyps in 3 (3.3%) patients (the mean diameter: 4.5±0.5 mm, range: 4-5 mm). Among the patients with gallstones and gallbladder polyps, 7 (63.6%) were female and 4 (36.4%) were male (p=0.141). The mean age was 53.73±13.32 years in patients with gallstones and gallbladder polyps and 48.24±13.40 years in those who had neither (p=0.094). Gallbladder wall thickening (4 mm) and echogenicities in the gallbladder wall (cholesterolosis) were detected in 1 (1.1%) patient. An increase in the transverse diameter of the gallbladder (42 mm) and accompanying gallbladder wall thickening (6 mm) were detected in 1 (1.1%) patient. Furthermore, kidney cysts were detected in 16 (17.8%) patients (the mean diameter: 26.5±15.8 mm, range: 8-50 mm). Increased echogenicity of kidney parenchyma was detected in 5 (5.5%) patients. The mean ages of the patients with and without kidney cysts were 56.81±7.54 years and 47.20±13.85 years, respectively (p=0.008). Kidney stones were detected in 4 (4.4%) patients (the mean diameter: 7.5±5.8 mm, range: 3-16 mm). Lobulated kidney contour was detected in 4 (4.4%) patients. Dilated renal collecting system was detected in 3 (3.3%) patients, focal caliectasis was detected in 1 (1.1%) patient, increase in kidney size was detected in 1 (1.1%) patient, decrease in kidney size was detected in 1 (1.1%) patient and a renal angiomyolipoma was detected in 1 (1.1%) patient. Abdominal ultrasonography also revealed increase in spleen size in 7 (7.8%) patients (the mean craniocaudal length: 13.87±1.05 mm, range: 13-16 mm), accessory spleen in 2 (2.2%) patients, splenic cyst with a diameter of 7 mm in 1 (1.1%) patient, situs inversus totalis in 1 (1.1%) patient, calcifications in prostatic parenchyma in 1 (1.1%) patient, heterogeneous prostatic parenchyma in 1 (1.1%) patient, an ovarian cyst measured 33x27 mm in size in 1 (1.1%) patient, uterine myoma with a diameter of 11 mm in 1 (1.1%) patient, increased bladder wall thickness (6 mm) in 1 (1.1%) patient, echogenic debris within the bladder which might be compatible with urinary tract infection in 1 (1.1%) patient (Table 2).

Based on ultrasonography findings, abdominal computed tomography (CT) was performed in 3 (3.3%) patients for further evaluation of kidney cysts and abdominal magnetic resonance imaging (MRI) in 2 (2.2%) patients for hypoechoic liver lesions and liver cysts. Renal scintigraphy was performed in 1 (1.1%) patient for the dilation of the renal collecting system.

DISCUSSION

Within this study, the most common abdominal ultrasonography finding in patients with psoriasis was increased echogenicity of the liver parenchyma due to steatosis (58.9%). Hepatic steatosis was more frequent in older patients, patients with diabetes, and patients who were previously treated with biological agents (p<0.001, p=0.007, p=0.007, respectively). These results may be related to the fact that patients previously treated with biologic agents were older than biologic-naive ones (p=0.021). In addition, increased echogenicity of the liver parenchyma due to steatosis was moderate or severe in 50.9% of the patients and most of these patients (70.4%) were female. An increase in liver size (25.6%) was the other common abdominal ultrasonography finding followed by kidney cysts (17.8%), gallstones (8.9%), and an increase in spleen size (7.8%). The increased liver size was statistically significantly more prevalent in female patients, and patients with psoriatic arthritis and hypertension (p=0.013, p=0.008, p=0.023, respectively).

Table 2: Abdominal ultrasonography findings in patients with psoriasis before biological agent treatment

	Patients n (%)	Mean size±SD (mm)	Range (mm)
Increased liver parenchyma echogenicity	53 (58.9)		
Increased liver size	23 (25.6)	16.69±0.96	15.5-20
Kidney cysts	16 (17.8)	26.5±15.8	8-50
Gallstones	8 (8.9)	15±7.05	3-20
Increased spleen size	7 (7.8)	13.87±1.05	13-16
Increased kidney parenchyma echogenicity	5 (5.6)		
Heterogeneous liver parenchyma	5 (5.6)		
Kidney stones	4 (4.4)	7.5±5.8	3-16
Lobulated kidney contour	4 (4.4)		
Hypoechoic areas in the liver	4 (4.4)		
Liver cyst	3 (3.3)		
Liver hemangioma	3 (3.3)		
Gallbladder polyps	3 (3.3)	4.5±0.5	4-5
Dilated renal collecting system	3 (3.3)		
Accessory spleen	2 (2.2)		
Gallbladder wall thickening	2 (2.2)		
Echogenicities in the gallbladder wall	1 (1.1)		
Focal caliectasis	1 (1.1)		
Echogenic debris within the bladder	1 (1.1)		
Increased kidney size	1 (1.1)		
Decreased kidney size	1 (1.1)		
Renal angiomyolipoma	1 (1.1)		
Increased bladder wall thickness	1 (1.1)		
Splenic cyst	1 (1.1)		
Uterine myoma	1 (1.1)		
Ovarian cyst	1 (1.1)		
Heterogeneous prostatic parenchyma	1 (1.1)		
Calcifications in the prostatic parenchyma	1 (1.1)		
Chilaiditi syndrome	1 (1.1)		
Situs inversus totalis	1 (1.1)		

SD: Standard deviation. An increase in echogenicity of the liver parenchyma due to steatosis was the most common abdominal ultrasonography finding in patients with psoriasis.

Data on abdominal ultrasonography findings in patients with psoriasis treated with biological agents are scarce. Raudonis et al. reported that hepatic and pancreatic steatosis, hepatomegaly, kidney cyst, splenomegaly, gallbladder polyp, and pancreatic stiffness were commonly detected findings in abdominal ultrasonography which were annually performed in patients with psoriasis treated with infliximab, etanercept, and ustekinumab. Among them, hepatic steatosis (12.7%) and pancreatic steatosis (12.7%) were the most common [13].

Nonalcoholic fatty liver disease is a metabolic disorder that may present with steatosis, and nonalcoholic steatohepatitis and may result in cirrhosis or hepatocellular carcinoma [14-16]. Advanced age and diabetes are the risk factors for the development of nonalcoholic fatty liver disease, whereas the effect of gender on disease remains controversial [17]. In addition, nonalcoholic fatty liver disease is more common in psoriasis patients with a prevalence of up to 65% compared to the general population [15]. Furthermore, poor prognosis has been reported in patients with nonalcoholic fatty liver disease accompanied by psoriasis [14,15]. Dermatologists are recommended to perform abdominal ultrasonography for screening fatty liver in patients with psoriasis, particularly in those who have metabolic syndrome even without elevated liver enzyme levels [6]. Dermatologists must determine accompanying nonalcoholic fatty liver disease in patients with psoriasis to choose appropriate treatment options. Dermatologists should also encourage patients for lifestyle changes or refer them to a gastroenterologist if needed [16]. For instance, Campanati et al. suggested that weight gain during anti-TNF-α treatment might increase the risk of hepatic fibrosis in psoriasis patients with nonalcoholic fatty liver disease [18]. Medications that may contribute to steatosis should be omitted in these patients. However, no specific treatment has been reported or primarily recommended for the treatment of psoriasis patients with nonalcoholic fatty liver disease [16]. On the other hand, TNF-α inhibitors such as adalimumab, etanercept, and infliximab may lead to hepatotoxicity. Among them, infliximab was the most commonly implicated one in the development of adverse effects on the liver such as jaundice, hepatitis, acute liver failure, cholestasis, and autoimmune hepatitis [19]. Even mild and rare, hepatotoxicity has been detected in patients who received ustekinumab [20].

Abdominal ultrasonography may be useful in patients with psoriasis since psoriasis has been associated with nonalcoholic fatty liver disease or intraabdominal malignancies such as hepatocellular carcinoma, gastric cancer, bladder cancer, lymphoma of the stomach and colon adenocarcinoma [21,22]. Intraabdominal malignancy and infections have also been reported in patients who received biological agents for the treatment of psoriasis. For instance, Nosotti et al. reported a 59-year-old male patient with psoriasis treated with adalimumab and diagnosed with B cell lymphoma with gastric, splenic, hepatic, abdominal lymph node, and vertebral involvement. Nosotti et al. suggested that the risk for the development of abdominal lymphoma should be kept in mind in patients with psoriasis under biological agent treatment. Nosotti et al. recommended performing abdominal ultrasonography before and during biological agent treatment for psoriasis [9]. Fortaleza et al. reported a 43-year-old male patient with psoriasis who developed splenic tuberculosis under infliximab treatment. Fortaleza et al. stated that close follow-up of patients treated with TNF-α inhibitors on the risk for extrapulmonary tuberculosis and disseminated tuberculosis was crucial [23]. Bud et al. reported peritoneal tuberculosis in a 32-year-old patient who received adalimumab for the treatment of psoriasis vulgaris. The patient had multiple splenic lesions on computed tomography of the abdomen and underwent surgery due to an initial diagnosis of a possible malignancy. Bud et al. suggested that Quantiferon test, abdominal ultrasonography, and computed tomography might be performed to exclude intestinal tuberculosis in patients with gastrointestinal symptoms treated with TNF-α inhibitors [24].

CONCLUSIONS

We suggest that patients with psoriasis should undergo abdominal ultrasonography before biological agent treatment not only to exclude intraabdominal malignancy and infections but also to determine hepatic steatosis. It should be kept in mind that nonalcoholic fatty liver disease has an asymptomatic course and poor prognosis in patients with psoriasis. Since lifestyle modification and weight loss can reverse early stages of nonalcoholic fatty liver disease such as steatosis [25], early detection of hepatic steatosis is crucial in the treatment of patients with psoriasis. Therefore, we suggest that abdominal ultrasonography should be performed in patients with psoriasis before biological agent treatment, especially in females, patients with advanced age, patients who were previously treated with biological agents, and patients with comorbidities such as diabetes. In addition, considering the high frequency of nonalcoholic fatty liver disease in patients with psoriasis, the most appropriate biological agent treatment should be determined in this population and stated in psoriasis treatment guidelines.

Abstract: *The most common problem of modern medicine is the development of increasing antifungal drug resistance nowadays including fungal infections of the skin and its appendages caused by dermatomycetes, yeast-like fungi, and molds so, there will be a need for alternative antifungal treatment. Natural substances with high antifungal properties like essential oils and their components show potential in this regard. Citrus lemon and Citrus sinensis essential oils were screened against Malassezia furfur by disc diffusion method and Minimum Inhibitory Concentration was determined by Modified Microdilution method. Citrus lemon (lemon) and Citrus sinensis (orange) show excellent inhibitory effects on the lipophilic, yeast-like fungus Malassezia furfur which causes Pityriasis versicolor, a chronic superficial fungal disease of the skin. The diameter of the inhibition zone was found to be 70 mm and 60 mm respectively. Malassezia furfur was found to be resistant against Clotrimazole & Ketoconazole. The minimum inhibitory concentration (MIC) of lemon and orange oil against Malassezia furfur was found to be 0.6 µl/ml and 0.8 µl/ml. These findings concluded that the use of Citrus lemon (lemon) and Citrus sinensis (orange) oil showed remarkable and excellent antifungal activity, and can be used as a traditional herbal medicine for the control of Pityriasis versicolor infection of the skin after undergoing clinical trials.*

Keywords: *Pityriasis versicolor, skin, Malassezia furfur, Citrus lemon and Citrus sinensis oils*

INTRODUCTION

Pityriasis versicolor (PV) is a superficial mycosis, that affects the superficial layer of stratum corneum [1]. The causative organism is Malassezia furfur, a yeast-like lipophilic fungus. Previously the mycelial form was called either Pityrosporum ovale or Pityrosporum orbiculare [2]. In 1951, Gordon isolated the organism M.furfur and renamed it P.orbiculare. It was recognized that M.furfur is the correct name and that P.orbiculare and P.ovale are synonyms [3]. The disease is most prevalent in early adulthood and small children are rarely affected [4-5]. PV is common in the post-pubertal age where sebaceous glands are active and in individuals who sweat more [6]. The prevalence in colder climates is less than 1% [7]. M. furfur is a component of normal skin flora in more than 90% of adults living in tropical areas [8]. Infectious diseases account for a high proportion of health problems in developing countries including India. Microorganisms have developed resistance to many antibiotics and as a result, immense clinical problem in the treatment of infectious diseases has been created [9]. The resistance of the organisms increased due to the indiscriminate use of commercial antimicrobial drugs commonly used for the treatment of infectious diseases. This situation forced the researchers to search for new antimicrobial substances from various sources including medicinal plants [10-11]. A survey of the literature reveals that many essential oils possess antifungal activity. Therefore, we need to search for plant-derived antifungal drugs which are safe and without side effects. Herbal medicines may be in the form of powders, liquids, or mixtures, which may be raw or boiled, ointments, liniments, and incisions [12]. Essential oils have been screened for their potential uses as alternative remedies for the treatment of many infectious diseases [13]. Essential oils have been shown to possess antibacterial, antifungal, antiviral, insecticidal, and antioxidant properties

[14-15]. Numerous essential oils have been tested for both in vitro as well as in vivo antifungal activity and some pose much potential as antifungal agents. Studies on the antimicrobial, especially antibacterial and antifungal activity of lemon grass oil and its components were reported [16-18]. Orange oil was composed principally of d-limonene, at 94%, and myrcene at about 3%. The essential oils of lemon and orange exhibited antifungal activity against common molds Aspergillus niger, A.flavus, Penicillium chrysogenum, and P.verrucosum. In the present study, the antifungal activities of lemon and orange oils were investigated to discover the medicinal potential of these oils for future application as an antifungal agent for Pityriasis versicolor disease.

MATERIALS AND METHODS

Extraction and Preparation of Oil

In the summer season, extraction of oil from the peels of lemon (Citrus lemon) and orange (Citrus sinensis) was carried out by standard hydrodistillation method, Clevenger's apparatus, and all operations were carried out at room temperature. The fresh peels of lemon and orange were washed to remove soil and sliced. Sliced pieces of fresh peels of lemon and orange (250 g) were placed in a separate flask, together with distilled water (1 L). After 5-6 hours, oil was collected from the apparatus, anhydrous with sodium sulfate for removal of water traces, then this 100% pure essential oil was dispensed into dark bottles and stored at 4°C until used. Essential oil was ready to use for disc diffusion and determination of MIC.

Screening of essential oil using Disc Diffusion method

Oil was screened for its antifungal activity against M.furfur by disc diffusion method [19]. Standard size Whatman No.1 filter paper discs, 6.0 mm in diameter, sterilized by dry heat at 140°C in an oven for one hour were used to determine antifungal activity. SDA medium for the disc diffusion test was prepared. After sterilization, it was poured into sterilized Petri plates and allowed to solidify. Then one day old, fresh culture of yeast will be used for inoculum preparation. A suspension that was just turbid (~0.5 McFarland standard) by visual inspection was prepared by suspending yeast in 0.9% NaCl solution and the homogeneous suspension was used for inoculation. Using a sterile cotton swab, yeast cultures were swabbed on the surface of sterile Sabourauds dextrose agar plates. Sterilized filter paper discs were soaked in neat, undiluted (100%) concentration of oils. Using ethanol-dipped and flamed forceps, oil-saturated discs of 100% concentration were aseptically placed over Sabourauds dextrose agar plates seeded with the respective test microorganism. The antibiotic discs of Clotrimazole and Ketoconazole (10 mcg/disc) were also aseptically placed over the seeded Sabouraud's dextrose agar plates as a standard drug for comparison of antifungal activity of lemon and orange oils. The plates were incubated at 37ºC for 24 hours. The diameter of the inhibition zones was measured in mm. Three replicates were kept in each case and average values were calculated. The activity of oils was measured by the following formula:

AI (Activity index) = Inhibition zone of sample/Inhibition zone of standard

Determination of Minimum inhibitory concentration using Microdilution method

The modified microdilution method by Provine and Hadley (2000) was followed to determine MIC [20]. Media used for MIC was semisolid agar media (Brain Heart Infusion Agar) aliquots of semisolid agar media (Bacto Agar; Difco Laboratories) at a pH of approximately 7.4 were poured into a 16-by 125-mm glass tube and autoclaved. A suspension that was just turbid (~0.5 McFarland standard) by visual inspection was prepared by suspending the selected fungi in 0.9% NaCl solution, vortexing, and homogeneous suspension was used for inoculation. Different concentrations of lemon and orange oils were added in media containing test tubes, afterwards a standard platinum loopful (~0.001 ml, Himedia, Flexiloop) of the inoculum suspension was inserted deep into each tube of medium containing a different concentration of oils, as well as an oil-free control, by a centered down-up motion to form a two-dimensional inoculum. The tubes were then incubated at 30OC for 48 hours to determine the MIC. MIC was read to be the lowest concentration at which there was no visible growth of the organism. Then, by visual inspection, good growth of the respective fungi in an oil-free medium as a control was detected (48 hrs for yeasts). Afterward, the growth in all tubes at different concentrations of lemon and orange oil was compared with that of the oil-free control to determine inhibition.

RESULTS

In our present work, M.furfur was found main etiological agent of Pityriasis versicolor disease hence antimycotic studies were carried out on M.furfur (Figure 1). The conventional treatment of fungal disease is limited, and part of the reason is due to the limited spectrum of the current antifungal drugs, and the expensive treatment, particularly due to the need for prolonged therapy. Thus, new drugs and alternative therapies are necessary, including natural products. We report here the antimycotic study of lemon and orange oil against M.furfur in vitro (Figure 2). The results of the present work on the antifungal activity of lemon and orange oil against M. furfur studied by two methods i.e Disc diffusion and Microdilution method are presented in Tables 1, 2, and 3.

Table 1: Antifungal activity of lemon and orange oil against Malassezia furfur

Essential Oil	Test Strain	IZ of Essential Oil
C. limon	*Molassezia furfur*	70 mm
C. sinensis	*Molassezia furfur*	60 mm

Table 2: MIC of C. limon oil against Malassezia furfur

Test Strain	Different concentrations of lemon Oil used in µl/ml	Growth visually inspected in different concentrations of oil
Malassezia furfur	0.1	+4
	0.2	+3
	0.3	+3
	0.4	+2
	0.5	+1
	0.6	0
	0.7	0
	0.8	0
	0.9	0
	1	0
	Control without oil	100% growth

Growth was scored in the following manner: *4+, growth comparable to that of the oil free control; 3+, growth approximately 75% that of the control; 2+, growth approximately 50% that of the control; 1+, growth 25% or less that of the control; and 0, no visible growth*

Table 3: MIC of C. sinensis oil against Malassezia furfur

Test Strain	Different concentrations of lemon Oil used in µl/ml	Growth visually inspected in different concentrations of oil
Malassezia furfur	0.1	+4
	0.2	+3
	0.3	+2
	0.4	+2
	0.5	+1
	0.6	+1
	0.7	+1
	0.8	0
	0.9	0
	1	0
	Control without oil	100% growth

Growth was scored in the following manner: *4+, growth comparable to that of the oil free control; 3+, growth approximately 75% that of the control; 2+, growth approximately 50% that of the control; 1+, growth 25% or less that of the control; and 0, no visible growth*

In our study, lemon and orange oils presented higher diameters of inhibition zones. The diameter of the inhibition zone obtained against lemon and orange oil at 100% concentration of pure oil was 70 mm and 60 mm respectively by disc diffusion method (Figure 3). According to our study by comparing with the reference drugs, lemon and orange oil was found to be more effective in inhibiting the growth of M. furfur. Clotrimazole and ketoconazole were found to be resistant to Malassezia furfur (Figure 4). Results of MIC of lemon and orange oils against M. furfur. are summarized in Tables 2 and 3. The results show that the lemon and orange oil exhibited inhibitory action at 0.6 µl/ml and 0.8 µl/ml concentrations against M. furfur. Both oils can be used for the development of natural antifungal agents against Pityriasis versicolor infections.

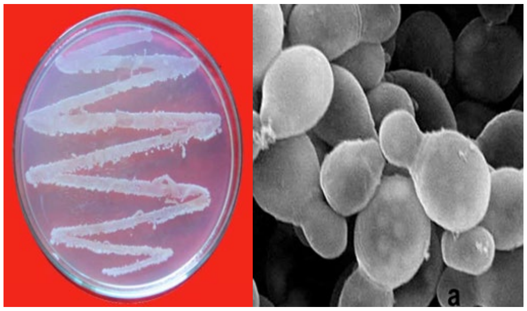

Figure 1: M. furfur on SDA media with olive oil & Bottle shape yeast cells under microscopic examination

Figure 2: Fruit of Citrus lemon (lemon) & Citrus sinensis (sweet orange)

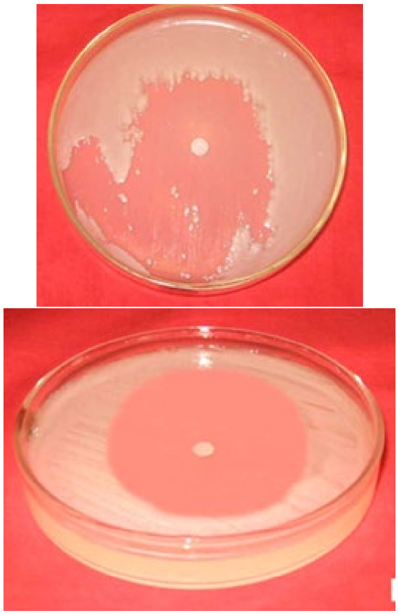

Figure 3: Antifungal activity of C. lemon & C. sinesis against Malassezia furfur

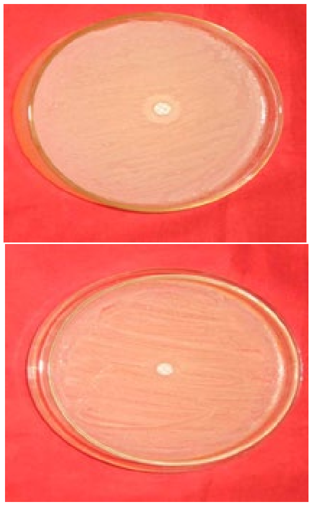

Figure 4: Resistance of Clotrimazole & Ketoconazole against Malassezia furfur

Their mechanism of action appears to be predominantly on the fungal cell membrane, disrupting its structure causing leakage and cell death; blocking the membrane synthesis; and inhibition the spore germination, fungal proliferation, and cellular respiration [22]. Because of the high volatility and lipophilicity of the essential oils, they are readily attached to penetrate the cell membrane to exert their biological effect [23]. The results showed the efficacy of lemon oil on animal skin infections caused by Trichophyton rubrum and Microsporum gypseum. In our study, lemon oil exhibited strong antimycotic activity against M. furfur. In the screening of lemon oil, the diameter of the inhibition zone by the disc-diffusion method was found to be 50 mm. MIC of oil obtained by microdilution method was 0.8µl/ml. Our work is in agreement with the observations of Silvia et al in which screening of lemon grass oil against Candida species was studied and it was found as an effective antifungal agent [24]. Our work also coincides with the previous findings of Ezzat et al which revealed that the essential oil of Citrus lemon at 200 µl concentration showed a diameter of inhibition zone 37 mm against Candida albicans 10261 [25]. According to Rusenova and Parvano Citrus lemon does not show antimicrobial activity by disc-diffusion method against both yeasts, Candida albicans and Malassezia pachydermatis [26]. These results are not in agreement with our studies which showed that antifungal activity by disc-diffusion and minimum inhibitory concentration by microdilution method, lemon oil was found to be effective in inhibiting the growth of M. furfur at a low concentration of oil. Lemon oil is also preferentially more active against Gram-positive bacteria as compared to Gram-negative bacteria. The antimicrobial activity of lemon oil is due to the presence of terpenoids-a-pinene, camphene, b-pinene, sabinene, myrcene, terpinene, b-bisabolene, limonene, trans-a-bergamotene, nerol and neral [27]. Essential oils from citrus offer the potential for all-natural antimicrobials for use in improving the safety of organic or all-natural foods [28]. Shahi et al in 2003 found that the MIC of oil of Citrus sinensis were in the range of 0.7-1 µl/ml against Candida albicans, Aspergillus flavus, A. fumigatus, A. niger, A. ustus, Epidermophyton floccosum, Microporum audouinii, M. canis, M. gypseum, M. nanum, Rhizopus nigricans, Trichophyton tonsurans, T. rubrum, T. mentagrophytes and T. violaceum [29]. The present investigation suggests that essential oils exhibit a narrow or wide range of antifungal activity, which may prove useful in the development of effective antifungal substances. Souza et al (2005) reported MIC of lemon oil at 0.5% concentration against mold strains i.e. Fusarium spp, Penicillium spp, Aspergillus niger, A. flavus, and Rhizopus spp [30]. In our findings, MIC of lemon oil against M. furfur was 0.8 µl/ml i.e. very close to that concentration. The small differences may be due to local environmental and climatic conditions and variations in the choice of microorganism tested.

Our results of orange (Citrus sinensis) and lemon (Citrus lemon) are also similar to the work of Viuda-Martos et al which suggests that both oils were effective in inhibiting the growth of Aspergillus niger, A.flavus, Penicillium chrysogenum and P. verrucosum [18]. The hydrodistilled oil of lemon and orange was also found to be more sensitive against Penicillium digitatum [31]. Antimicrobial activity of Rutaceae family species has been observed on dermatophytes [32] and on some molds [33]. Essential oils of some plants have recently been proven to be successful eco-friendly, bio-control agents [34]. Many authors have reported antimicrobial, antifungal, antioxidant, and radical-scavenging properties of essential oils [35-36].

DISCUSSION

The present results suggest that lemon and orange oils exhibit strong antifungal activity. This is in agreement with the findings of Valero and Frances who reported narrow and wide ranges of antifungal activites. Essential oils derived from many plants are known to possess antifungal activities [21].

CONCLUSIONS

The present study suggests that the oils extracted from the waste product (peels) of C. sinensis and C. lemon hold good promise as an antifungal agent, which could be used in therapeutic remedy against human pathogenic fungi on account of its various antifungal properties, viz. strong fungicidal action, long-shelf life, withstand heavy inoculum density, thermostable, broad range of antifungal activity and absence of any adverse effects. The waste product of C.

sinensis and C. lemon can be used for the development of a potential source of effective and economically viable herbal antifungal against Pityriasis versicolor (fungal skin infection) after undergoing successful clinical trials.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research received no external funding.

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers may cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor may not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Editor-in-Chief. The Editor-in-Chief reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at: http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

– Accessible to the public at no charge;

– Searchable by standard, electronic (Internet-based) methods;

– Open to all prospective registrants free of charge or at minimal cost;

– Validates registered information;

– Identifies trials with a unique number; and

– Includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, a target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The Journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 200 words. Abstracts for original articles should be formatted as detailed in the word form. Titles must not be longer than 120 characters (including spaces). In every article, there must be three to ten pertinent keywords specific to the article yet reasonably common within the subject discipline.

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article. This should be cited as Rom. J. Mil. Med. (year); (vol): [issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related “miniseries” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this

avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are suggested to limit to 3000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Executive Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate.

Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication, as presented at http://www.ICMJE.org/.

Spelling

The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units

All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations

Abbreviations should be used sparingly and only where they ease the reader's task by reducing the repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: the title page; the main text file according to the word model.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or an article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented according to the word model. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 200 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. If appropriate, divide the abstract with the headings: Background and Aim, Methods, Results, and Conclusions. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to ten keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser – http://www.nlm.nih.gov/mesh/meshhhome.html.

Text

Authors should use the word form in editing the submitted material.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square parentheses in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or fewer; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

Use Index Medicus as the style guide for references and other journal abbreviations.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table and legend must be

understandable without reference to the text. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, •, ‣ should be used (in that order) and *, **, *** should be reserved for P-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication:

Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com. A cover letter containing an authorship statement should be included. The cover letter should include a statement covering each of the following areas:

– Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author. It is not accepted the idea of equal contribution.

– Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.

– A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

– For research involving pharmacological agents, devices, or medical technology, a clear Conflict of Interest statement about any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

– For clinical trials, these have been registered in a publically accessible database (see more under ‘ETHICAL CONSIDERATIONS (Further Information)’ later in these guidelines).

If the above items are not included in the cover letter, manuscripts cannot be sent for review. Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section ‘Parts of the manuscript’, including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using the word model that is to be found on the web page (http://revistamedicinamilitara.ro/wpcontent/uploads/2022/07/Macheta-articole.docx).

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, high-resolution figures (at least 300 d.p.i.) saved as .eps, .jpg or .tif files are required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted Articles

Accepted Articles are published online after final acceptance, and appear in PDF format only.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing the proof of acceptance. It is therefore essential that a working e-mail address is provided for the corresponding author.

COPYRIGHT, LICENSING, AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is submitted.

Abstract: *More and more research in recent years has focused on neurogenesis and neuroplasticity. The hippocampus is a key location of adult neurogenesis. Because this part of the brain is regulated by environmental variables, it must be mentioned the therapeutic potential for neurodegenerative illnesses and brain injuries. Furthermore, this information challenges the historical concept of a static brain and tries to demonstrate its flexibility, adaptability, and possibility for regeneration. Those mechanisms which are found in a variety of mammalian species, including humans, are important when it comes to adaptive learning and memory, thus providing insights into cognitive well-being and mental health. The discovery of the brain's dynamic nature represented by new neurons, marks a shift in the field of neurology with far-reaching potentials. This paper highlights the significant potential of adult neurogenesis when it comes to clinical applications such as Alz-heimer's disease.*

Keywords: *adult neurogenesis; neurodegeneration; neuroplasticity; therapeutical approaches; Alzheimer's disease; hippocampus; ethanol exposure*

INTRODUCTION

From a historical perspective, the brain was frequently defined as a static organ post-development. That means that most of its structures and also its functions are established during the early years of life [1]. This belief was held due to the absence of knowledge regarding neurogenesis, defined as the development of new neurons. The way we understand brain function, its plasticity, and the potential for recovery after an injury has been impacted by this perspective [1].

During the 1960s, remarkable contributions by Altman and Das provided convincing support for the occurrence of neurogenesis in certain regions of the adult rat brain, particularly in the hippocampus [2]. Although these statements led to various debates in the field of neurology, they also initiated a significant change in the way neurosciences is understood.

Based on the latest research, the hippocampus is deeply involved in not only the process of memory formation but also in spatial awareness processes [3-5]. The study of this process at the level of the dentate gyrus has yielded even more insights regarding the brain's innate possibility of self-repair. Neurogenesis also influences cognitive processes such as learning, memory, and mood regulation [6-9].

Advanced techniques ranging from neural imaging to molecular biology were used. The primary objective of these investigations was to ascertain the specific circumstances that facilitate neurogenesis. It is also essential to comprehend the role played by the newly formed neurons and explore the external factors that impact neurogenesis. Researchers have analyzed the effect of stimulating environments and physical activity on this process.

The more robust the evidence supporting adult neurogenesis was discovered, the more researchers became aware of its potential consequences for human health. The inquiry arises as to whether neurogenesis can be utilized for therapeutic purposes, i.e., "What are the possible effects on conditions characterized by neuronal degeneration, such as Alzheimer's disease or traumatic brain injuries?" The scientific community is enthusiastic and motivated about the potential use of adult neurogenesis for treating diverse neurological and psychological disorders [10].

MATERIALS AND METHODS

A rigorous methodology was employed in this narrative review to gather, analyze, and synthesize scholarly literature on adult neurogenesis. Due to the abundance of available research, we employed a systematic approach to thoroughly examine the most relevant and up-to-date studies.

Our analysis involved articles that explored the concept of neurogenesis in adult mammals, their intricacies, implications, and potential therapeutic applications. We methodically sourced diverse academic articles, primarily from PubMed, Scopus, and Google Scholar, ensuring a comprehensive exploration. We searched for various aspects of neurogenesis using both broad and specific search terms, and we prioritized recent research while recognizing foundational studies.

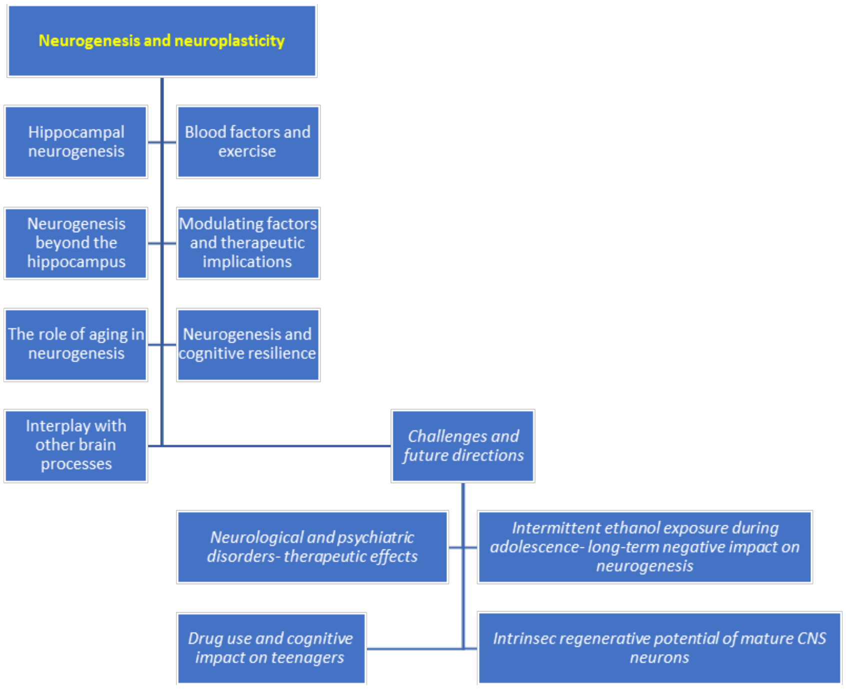
FROM NEUROGENESIS TO NEUROPLASTICITY

Adult neurogenesis is a process involving the formation of new neurons. The process takes place in the mature brain. It has been a topic of intense examination and debate in neuroscience [4,11]. While it is accepted that mammals, particularly rodents, exhibit this phenomenon in their hippocampus, the occurrence of such a process in humans has been controversial [1,12].

Historically, the mature mammalian Central Nervous System (CNS) was believed to possess limited regenerative potential. However, emerging evidence challenges this perspective, proposing that the mature CNS, including that of humans, might harbor a latent regenerative ability influenced by environmental factors [13,14]. Moreover, the adult hippocampal neurogenesis (AHN) observed in rodents is not merely an isolated phenomenon. It manifests neural plasticity prevalent across many mammalian species, including humans. Based on all this information, it is worth mentioning the fact that plasticity which is essential for both memory processes and also adaptive learning, is now starting to shift our understanding of the capabilities of the human brain [12,15-18].

Due to that, further researchers in the field of adult neurogenesis are perceived as being essential. Some of the potential consequences that are highlighted in the literature include an enhancement of cognitive well-being together with the potential of using it as a form of treatment strategy. As this topic becomes more and more prevalent in scientific literature, the current aim is to recognize neurogenesis complexities across different species and try to apply these notions to human brain health and the potential pathologies that might arise at this level.

Based on the results of the current literature review, the most relevant themes referring to neurogenesis and neuroplasticity were clustered into 12 categories (Figure 1).



Neurogenesis and neuroplasticity
Hippocampal neurogenesis
Blood factors and exercise
Neurogenesis beyond the hippocampus
Modulating factors and therapeutic implications
The role of aging in neurogenesis
Neurogenesis and cognitive resilience
Interplay with other brain processes
Challenges and future directions
Neurological and psychiatric disorders- therapeutic effects
Intermittent ethanol exposure during adolescence- long-term negative impact on neurogenesis
Drug use and cognitive impact on teenagers
Intrinsec regenerative potential of mature CNS neurons

Figure 1: Neurogenesis and neuroplasticity – paradigm shifters in understanding the brain's functionality

Hippocampal Neurogenesis

Regarding the concept of neurogenesis, the primary focus was on the function of the hippocampus, particularly the area known as the dentate gyrus [7,8,19-22]. This is because, from a historical perspective, this region was frequently mentioned as being associated with various important cognitive functions. It is essential in memory formation, spatial awareness, and emotional control. Discovering neurogenesis in this region has reevaluated our understanding of its importance [2,7].

The incorporation of new neurons into existing hippocampal networks boost plasticity. This could also lead to enhanced cognitive functions. For instance, studies on rodents have shown a positive link between increased neurogenesis and better performance in spatial memory tasks [3,4,5,20,23-26]. Additionally, evidence points to a relationship between disruptions in neurogenesis and mood disorders. This claim suggests a potential link between creating new neurons and emotional regulation [9].

Blood Factors and Exercise

The influence of the environment on neurogenesis is becoming a significant research focus [27]. Evidence suggests that elements present in the bloodstream can affect the brain's ability to regenerate [28,29]. Notably, a study by Horowitz et al. [23] found that plasma from trained animals could transfer the beneficial effects of physical activity on neurogenesis to older individuals. This indicates that a systemic environment shaped by exercise can strengthen the brain's regenerative potential [23, 27].

Such discoveries are of great significance, particularly for the elderly. As concerns about cognitive decline with age intensify, it becomes crucial to grasp how systemic elements can enhance brain health [29]. These blood-derived factors might stimulate neurogenesis in those who can't partake in physical exercise [23].

Neurogenesis Beyond the Hippocampus

While the hippocampus remains a focal point, recent research has expanded the exploration of neurogenesis to other brain areas. Current scientific research has presented persuasive evidence for neurogenesis in various brain regions: hypothalamus, striatum, substantia nigra, cortex, olfactory bulb, and amygdala [28,30-32].

The potential functional impacts of neurogenesis in these areas are still under study. For instance, the striatum, involved in motor functions and reward-driven behaviors, might witness improved plasticity by new neurons. Similarly, neurogenesis in the amygdala, a key center for emotion processing, could shape how emotional memories and knowledge are acquired and stored [3-5,9,20,30].

Modulating Factors and Therapeutic Implications

Numerous intrinsic and extrinsic elements have been identified as influencers of neurogenesis. Neurotrophic factors, signaling molecules that aid neuron growth and differentiation, are known to boost neurogenesis [10,27,33-36]. For example, the Brain-derived neurotrophic factor (BDNF) plays a fundamental role in supporting the survival of new neurons by activating the tropomyosin receptor kinase B (TrKB) receptor, which then triggers pathways related to cell survival and movement [31,36].

Environmental elements, like being in stimulating surroundings or participating in cognitive activities, are associated with heightened neurogenesis [30,37]. Additionally, the development of new neurons in specific brain parts, remarkably in the context of brain injury (such as stroke) and neurodegenerative conditions, can be shaped by particular processes [38]. The importance of understanding neurogenesis is crucial for considering therapeutic approaches [10].

Furthermore, pharmacological interventions targeting specific signaling pathways involved in neuron differentiation offer promising possibilities. As research progresses, more targeted drug interventions might be elaborated to fine-tune the neurogenesis process, providing benefits in conditions where neural regeneration is needed [10,39].

Emerging research also implies that stem cell therapies could be employed to promote neurogenesis. Researchers aim to enhance the brain's regenerative capability, particularly in conditions marked by substantial neuron reduction. This could be achieved by introducing pluripotent stem cells that can differentiate into neurons. The potential of stem cell therapies lies in their ability to replace lost neurons and provide a supportive environment that promotes the growth of new neurons [14,40].

The Role of Aging in Neurogenesis

The implications for aging are one of the most compelling aspects of research on adult neurogenesis [23,24,26,29,41-44]. As individuals age, an inherent decline is observed in multiple cognitive domains. This is accompanied by a reduced brain ability to recuperate from injuries or diseases [45]. Identifying adult neurogenesis, particularly in older mammals, prompts inquiry into the potential harnessing or augmentation of regenerative capabilities in the aging brain [14].

Research has indicated a multifaceted association between the aging process and the generation of new neurons. Although there is an inherent decrease in the rate of neurogenesis with age, it is essential to note that this process does not come to a complete cessation [28]. The population of dormant stem cells in the hippocampal dentate gyri diminishes with advancing age. This happens while the number of actively dividing progenitor cells and immature neurons remains consistent over aging [7,8,28]. This observation implies that the brain maintains its regenerative capacity even during advanced stages of life. Furthermore, while neuroplasticity decreases in older individuals, the volume of granule cells (GCs), glia, and dentate gyrus remains unaltered [28,45].

Significantly, interventions such as exercise have demonstrated the capacity to counteract the process of brain aging [27]. Previous studies have observed that specific blood components present in the plasma of mice subjected to exercise can transmit the advantageous impacts of exercise on adult neurogenesis and cognitive function to mice that had a sedentary lifestyle [33]. The hepatic enzyme glycosylphosphatidylinositol (GPI)-specific phospholipase D1 (Gpld1) exhibited elevated levels following physical exertion. This molecule was associated with enhanced cognitive performance in elderly mice. In a promising manner, high levels of Gpld1 were likewise detected in the bloodstream of physically active and robust older individuals. According to Horowitz et al. [23], when administered systemically in aged mice, it can alleviate age-related impairments in regeneration and cognition.

Neurogenesis and Cognitive Resilience

An emerging area of interest is the role of neurogenesis in cognitive resilience. Cognitive resilience refers to the brain's ability to resist or recover from potential cognitive decline, often attributed to aging, injury, or disease [7,38,46-48]. Generating new neurons and their successful integration into existing neural networks could strengthen the brain's resilience. This adaptation allows the brain to maintain or enhance cognitive functions in the face of adversities [7].

This has implications for age-related disorders and conditions like traumatic brain injuries, stroke, or even chronic stress [38]. If neurogenesis can be stimulated and directed appropriately, it might offer a therapeutic strategy to counteract the cognitive deficits.

Interplay with Other Brain Processes

Neurogenesis is not isolated; it's intricately linked with other brain processes [37,49,50]. Synaptic plasticity, the capability of synapses to toughen or deteriorate over time, is believed to play a role in learning and memory [4]. Introducing new neurons into neural circuits could enhance synaptic plasticity, facilitating better learning and memory retention. Moreover, processes like long-term potentiation, critical for memory formation, might be influenced by new neurons, further emphasizing neurogenesis's role in cognitive functions [49].

Challenges and Future Directions

While the findings on adult neurogenesis are promising, challenges remain (Figures 1, and 2). The exact mechanisms regulating neurogenesis, the factors determining the survival and integration of new neurons, and the functional implications of these neurons are areas of active research [26,29]. Additionally, translating findings from animal models to humans presents its own set of challenges [52]. However, with continued research and technological advancements, the potential to harness neurogenesis for therapeutic benefits appears promising [10].

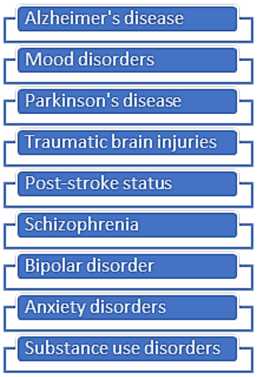


Figure 2: Potential targets of the neurogenic therapies

Implications for Neurological and Psychiatric Disorders

Identifying adult neurogenesis carries significant implications for neurological and psychiatric disorders [38,47,53-61]. Neurodegenerative disorders, such as Alzheimer's disease, are characterized by the loss of neurons. These may benefit from a deeper comprehension of the processes underlying neurogenesis [41,47]. Similarly, mood disorders like depression have been linked to decreased hippocampal volume and disrupted neurogenesis. These could also benefit from interventions aimed at promoting the generation of new neurons [4].

Furthermore, conditions such as Parkinson's disease and Huntington's disease, characterized by specific neuronal cell loss, could be targeted with neurogenic therapies. The interventions should replace the lost neurons or protect the remaining ones. Understanding the factors influencing intrinsic or extrinsic neurogenesis can pave the way for novel therapeutic strategies [57,62-66].

Traumatic brain injuries and strokes resulting in acute neuronal damage might also benefit from enhanced neurogenesis [44]. Strengthening the brain's inherent ability to generate new neurons could speed up recovery, improve cognitive function, and potentially restore lost skills [1].

Moreover, the implications of neurogenesis aren't limited to just the diseases that involve neuronal loss. The balance and health of neurogenesis might influence conditions like schizophrenia, bipolar disorder, and anxiety disorders—these disorders have an unclear etiology that is still under investigation. Disruptions in the process could contribute to the pathophysiology of these disorders [54].

Understanding how lifestyle choices, physical activity, the way we manage stress, and the approach dietary habits might impact the process of neurogenesis are also perceived as being essential to enhancing our understanding of this topic [51].

The impact of intermittent ethanol exposure during adolescence on the process of neurogenesis in the hippocampus

The adolescence period is a key point in neurology due to the high rate of both neuroplasticity and neurogenesis which characterizes it [67-73]. Despite this, during this maturational phase, many young people tend to engage in various risky behaviors such as consuming large amounts of alcohol and binge drinking [29,36,72]. Such behaviors, while transient for many, can have persistent consequences for brain health and function [36].

Recent studies that approached preclinical rodent models have shed light on the possible effects of adolescent intermittent ethanol (AIE) exposure [67]. These models have revealed an alarming pattern, especially because AIE was linked to a significant decrease in the formation of new neurons at the level of the hippocampus [33,36,67-73]. Notably, this decline doesn't merely correspond with the period of ethanol exposure. Instead, the detrimental effects persist into adulthood, even when ethanol exposure has ceased. This indicates a long-lasting impact on the brain's ability to produce new neurons [33].

Recent discoveries have pointed towards neuroimmune and epigenetic pathways. Increased neuroimmune signaling post-AIE exposure suggests an inflammatory response. This might inhibit the normal process of neuron generation [33]. Simultaneously, there's evidence of de-creased neurotrophic support. This implies that the usual signals promoting neuron growth and differentiation are compromised. Epigenetic mechanisms, characterized by modifications in gene expression that do not involve modifications to the underlying DNA sequence, have a crucial role in facilitating these effects. These mechanisms could alter the gene expression for neurogenesis, thereby perpetuating the decline in neuron generation [33,36].

Drug Use and Cognitive Impact on Teenagers

The brain, in particular, undergoes profound developmental processes that give rise to intricate behavioral and mental faculties. However, the trajectory of this development is not solely determined by biological factors; it is also susceptible to environmental influences. Among these, drug exposure is a particularly concerning factor that can derail neurobiological maturation [74-77].

Historically, the health implications of drug use during adolescence have been a subject of considerable concern [75,76]. The predominant focus has been understanding how adolescent drug use might predicate or correlate with drug-using behaviors in adulthood. However, recent scientific inquiries have expanded this focus, revealing that the ramifications of teenage drug use are not confined to future drug-related behaviors. Other behavioral domains, notably learning and memory, have been scrutinized [52].

Emerging evidence suggests that learning and memory are particularly vulnerable to the effects of drugs during adolescence [75]. More alarmingly, deficits in these cognitive domains, once established due to drug exposure, appear to persist into adulthood. These findings indicate a deep-seated interaction between drug exposure and the natural developmental processes of the adolescent brain. This interaction yields consequences that endure well beyond the cessation of drug use, emphasizing the gravity of the issue [74-76].

In light of these revelations, it becomes imperative to understand the exact nature and extent of the cognitive impairments caused by adolescent drug exposure. While the research landscape is vast, some patterns are discernible. Adolescents, due to societal norms and legal frameworks, are more inclined towards drugs that are legally accessible to adults. As such, alcohol, nicotine, and marijuana emerge as substances of primary concern [77,78].

Intrinsic Regenerative Potential of Mature CNS Neurons

For years, the broader field of neuroscience has operated under a prevailing assumption: that the neurons in the adult mammalian CNS possess limited if any, capacity for regeneration following injury. This perspective contrasts our understanding of peripheral nerves, which have consistently demonstrated a robust ability to regenerate after various forms of trauma [14].

Delving into the reasons behind this perceived inability of CNS neurons to regenerate, researchers have pinpointed a few key factors. Paramount among these is the presence of specific extracellular signaling factors in the CNS environment [28]. These factors inhibit axonal growth, blocking the natural regenerative processes that might otherwise occur. Furthermore, there's the notion that mature central neurons, as they age, may lack the adaptive responsiveness required to counteract and recover from damage. This idea aligns with a broader dogma in neuroscience, which suggests that as central neurons mature, they inherently lose their structural plasticity [14].

However, recent discoveries have started to challenge this traditional viewpoint. Emerging evidence suggests that the mature CNS might not be as rigid and unresponsive. More exactly, some of the neurons might be defined by a latent regenerative ability. This capacity might be masked by various environmental factors, but they continue to exist. If this capability can be better understood, it could reform the methodology of treating CNS injuries and neurodegenerative conditions [14].

CONCLUSIONS

The discovery of adult neurogenesis has enhanced our understanding of the concepts of brain plasticity and regeneration. Although we previously believed that the fully developed mammalian brain remained unchanged, this static paradigm was proven wrong based on new discoveries in the field of neuroplasticity and neuroregeneration.

However, the latest academic research in the field of neurosciences highlights that this is incorrect, as our brain is still able to produce new neurons and also can adjust itself based on various internal and external variables. This significant advancement has had a profound impact on various medical fields, as is the case of neurosciences and therapeutic practices regarding the brain.

The phenomenon of adult neurogenesis provides information that contradicts traditional beliefs as it highlights the ever-changing nature of the brain. The process is not limited to only the synaptic plasticity, as completely new neurons can develop. This implies a remarkable durability that provides optimism when it comes to treating patients with neurotrauma or neurodegenerative pathologies.

Therapies that promote neurogenesis might potentially be beneficial for diseases such as Alzheimer's and depression, both of them being conditions that are frequently associated with a significant loss of viable neurons. The understanding of the novel neuron generation process and how this could be modified and incorporated holds significant therapeutical possibilities.

It is also important to mention that the process of neurogenesis can be influenced by external factors such as physical activity. Based on this observation, structured physical exercises must also be considered when trying to facilitate neurogenesis in the case of the elderly population who are diagnosed with dementia and a cognitive decline [79-81]

The neural development of our brains may be significantly influenced not only by our previous experiences but also by the environment in which we live and the decisions we make, often to a greater extent than we are currently aware of. The entire concept of adult neurogenesis research still encounters persistent controversies. This is mostly due to the lack of understanding of this process which is frequently believed to be too complex at this stage or inadequately studied.

Abstract: *Eggshell calcifications at thyroid ultrasound are connected to the challenging field of thyroid nodules and/or malignancy from a multidisciplinary perspective. Calcifications may be found in malignant and benign tumors; typically, micro-calcifications are identified in the papillary type of cancer, being equivalent to psammoma bodies in the pathological report. The risk of macro-calcifications, however, is more nuanced; recent data suggest a potential connection with a differentiated malignancy as well. Eggshell calcifications, a distinct type of macro-calcification, are generally considered benign findings, especially uninterrupted forms. Yet, the real incidence is not clear, which is why the topic remains open. In this narrative review, we analyzed eggshell calcifications in relationship with cytological diagnosis upon fine needle aspiration and post-thyroidectomy histological report. A PubMed-based search of the English-language papers using several keywords identified 171 articles. We only included original studies (no timeline restriction). After removing duplicates and applying the inclusion and exclusion criteria, 14 original studies were analyzed. The number of subjects per study varied (N=61 to 2678) so did the number of analyzed nodules per study (a maximum of 2902). Some studies found connections with benign features; others revealed a higher risk of malignancy at fine needle aspiration. Data remain heterogeneous, and oftentimes, studies investigated it only as a secondary endpoint. A high TI-RADS score is important in malignancy prediction, while eggshell calcification might add to the positive predictive value, yet, this trait is difficult to classify as a standalone element. Nevertheless, an interrupted pattern does not exclude thyroid cancer.*

Keywords: *thyroid, ultrasound, calcification, thyroidectomy, surgery, thyroid nodule, thyroid*

INTRODUCTION

Eggshell calcifications amid thyroid ultrasound are connected to the challenging field of thyroid nodules and/or thyroid malignancy. Recently, an important rise in thyroid nodule detection was brought about by the widespread use of ultrasonography, with detection rates reaching 60% of the general population (noting that the general prevalence of a thyroid nodule is 5%) [1,2]. As a consequence, there was also an apparent increase in over-diagnosis of differentiated thyroid cancer [3]. The increased costs, risks associated with surgical cures such as hypoparathyroidism and dysphonia, and the fact that most thyroid carcinomas are indolent, led current guidelines to lean towards a more conservative and individualized approach to thyroid nodules [4-7]. However, even though the mortality rates of thyroid carcinoma remained stable despite an increasing incidence, this is in opposition to decreasing rates of other solid malignancies [8]. The need for adequate risk assessment of thyroid nodules, therefore, remains clear. The importance of approaching this type of ultrasound lesion comes from providing additional clues and even risk factors for suspected malignancies to assess these patients particularly or to start meticulous screening protocols. Moreover, nowadays, thyroid ultrasound is largely available to a multitude of specialists coming from different backgrounds thus the importance of identifying the risk (if any) behind such lesions [4-8].

Currently, there are several risk stratification systems for thyroid nodules, including the American College of Radiology

Thyroid Imaging Reporting and Data System (ACR TI-RADS) [9], the American Thyroid Association (ATA) guidelines [10], and the European Thyroid Association Guidelines for Ultrasound Malignancy Risk Stratification of Thyroid Nodules in Adults EUTIRADS [11]. All of them use similar sonographic characteristics to assess the risk of a thyroid nodule being benign or malignant.

Overall, calcifications may be found both in malignant and benign tumors. Findings such as spongiform or cystic nodules, with regular borders suggest benign nodules, while echogenic foci or micro-calcifications plead for malignancy [12,13]. Typically, micro-calcifications are found in malignant tumors and are the ultrasonographic equivalent of psammoma bodies (that are described in pathological reports) [14,15]. The risk of macro-calcifications, however, is more nuanced, but recent data suggest a possible connection with papillary carcinoma [16,17].

One particular type of peripheral macro-calcification, rim calcifications, which surround at least 120º of the nodule were found to be associated with malignancy [18,19]. Another type of macro-calcification is so-called “eggshell calcification”, a peripheral thin rim-like calcification surrounding the nodule. Typically, they are considered benign findings, especially when they are uninterrupted [20]. They may, however, be found in papillary carcinoma as well, but the real incidence is not yet clear, which is why the topic represents a challenging multidisciplinary approach in the modern era [21].

We aim to identify what type of lesions may present with eggshell calcifications on thyroid ultrasound, what risk of malignancy nodules with eggshell calcification have, and what other sonographic features help in elucidating diagnosis.

MATERIALS AND METHODS

This was a narrative review. A PubMed-based analysis of the English-language medical literature was conducted by using the following keywords: “eggshell”, “peripheral calcification”, “annular calcification”, and “curvilinear calcification” in association with “thyroid”.

The initial search resulted in 171 articles. We only included original studies (no timeline restriction).

Articles were included if they provided data regarding nodules with eggshell calcifications and were selected based on clinical relevance. Case reports and studies exclusively focusing on different types of peripheral calcifications or rim calcifications were excluded.

After removing duplicates and applying the inclusion and exclusion criteria, 14 original studies were analyzed.

RESULTS

Sample-focused analysis

Data regarding eggshell calcifications was heterogeneous, and, oftentimes, studies investigated the relationship between this distinct form of calcification as a secondary objective. The number of subjects varied largely, with the smallest study including 61 subjects and 64 nodules [22]; the largest had 2678 subjects and a total of 2902 nodules [23]. While some studies found connections with benign character [24,25], (others found a higher risk for suspicion of malignancy at fine needle aspiration (FNA) [26]. Some studies, however, did not find statistical significance [22,27-29].

Prevalence of eggshell calcifications amid thyroid ultrasound followed by thyroidectomy

The largest study was performed by Kobayashi et al. [23] and included 2678 subjects who underwent thyroid surgery and a total of 2902 nodules. 26% of nodules had calcifications. This study provided the prevalence of eggshell calcifications in different types of thyroid malignancies. The highest prevalence of eggshell calcifications, 43.90% (N=18/41), was found in undifferentiated carcinomas. In the papillary type of carcinoma, the prevalence was 4.78% (N=45/941), while in follicular carcinoma it reached 11.86% (N=40/337). In some malignancies, such as cyst-forming variants of papillary carcinoma, medullary carcinoma, and primary thyroid lymphoma, no eggshell calcifications were found [23]. The second largest study was conducted by Zayadeen et al. [30] and included 1466 patients and, respectively, 2002 nodules; eggshell calcifications were found in 45 benign nodules and in 11 malignant ones [30].

Eggshell calcifications and thyroid malignancy risk

Overall, no statistically significant association between eggshell calcifications and malignancy was found. However, a link between calcification subtype, namely discontinuous eggshell calcifications, and malignant tumors was reported [31]. Yin et al. [31] conducted a retrospective study on 543 subjects with single nodules who underwent thyroid surgery. Pathology results revealed that 61.32% (N=333) of them were malignant. The relationship between the presence of malignancy and various calcification types, including eggshell calcification, was analyzed. In terms of eggshell sub-type, eggshell in a row (continuous) forms were more frequent in benign nodules (1.7% versus 0.6%, p<0.01), while discontinuous eggshell calcifications were more frequent in malignant nodules (2.2% versus 0.6%, p<0.01). The distribution of calcification types among nodules prompts further studies investigating possible relationships between calcification types and different types of benign and malignant lesions. Of note, in benign nodules, all eggshell calcifications were found in adenomas, while in malignant nodules, all in-a-row calcifications were in medullary carcinoma (N=3/3), while discontinuous calcifications were found in papillary carcinoma (N=12, 3.84% of papillary carcinomas) [31]. Ha et al. [25] also found that nodules with eggshell calcifications are more frequently benign (66.7% benign versus 33.3% malignant, p=0.002) [25].

Another study investigating the connection between eggshell calcifications and malignancy risk was conducted by Arpaci et al. [26]. The study included 907 nodules of 269 subjects. Most were investigated via FNA (N=907). Even though benign nodules were less frequent in cases with eggshell calcifications compared with those without macro-calcifications, and suspicion for malignancy rates were higher in nodules with eggshell calcifications, no statistical significance was found for malignancy or diagnostic rates, based on cytology. Lack of statistical significance in terms of eggshell calcification presence in benign versus malignant nodules was also shown in patients who underwent surgery and had pathologic diagnoses [26]. Another study that failed to find statistical significance between the presence of eggshell calcifications and benign or malignant nodules was that of Lee et al. [22], which included 103 nodules in 92 patients. The diagnosis was made based on FNA and follow-up [22]. Kim et al. [27] did not find a statistically significant association either. However, the study described a prevalence of eggshell calcifications of 2.4% in malignant nodules and 5% in benign nodules, in a population of 1078 subjects with 1432 nodules who underwent thyroidectomy for nodular disease [27].

Yoon et al. [29] did not find a statistically significant difference between benign and malignant groups in terms of the presence and type of peripheral calcifications in a retrospective study on 65 subjects, most of whom were diagnosed by FNA [29]. Regarding differentiated papillary carcinoma in particular, Wang et al. [24] found that eggshell calcifications decreased the risk of papillary carcinoma (OR=0.208, CI=0.049-0.886, p=0.034). Moreover, they were not an independent risk factor for aggressive behavior [24].

Hashimoto's chronic autoimmune thyroiditis

Sonographic features of nodules in patients with Hashimoto's thyroiditis were analyzed by Anderson et al. [32] in 61 subjects with 64 nodules. Overall, eggshell calcifications represented 23% of all calcifications, appeared in 4.7% (N=3) of nodules, and were more frequent in subjects with normal parenchyma [32]. Another study by Anderson et al. [28] extended the search to 82 nodules of 78 subjects with Hashimoto's thyroiditis who underwent FNA or surgery. 84% (N=69) of nodules were benign, while 16% (N=13) were malignant, most of which were papillary carcinoma (N=12). One primary thyroid lymphoma was also found. Even though eggshell calcifications were present in 15% of malignant nodules and 1% of benign nodules, the difference was not statistically significant [28].

Neuroendocrine neoplasia

While eggshells in a row were present in medullary carcinoma in Yin et al.'s study [31], Kobayashi et al. [23] did not find any eggshell calcifications in the medullary type of malignancy [23]. The largest study analyzing eggshell calcification in patients with a form of thyroid cancer was performed by Cai et al. [33] on 27 cases and 50 controls. Even though macro-calcifications, in general, were more frequent in patients with medullary thyroid carcinoma, none of the 27 cases had eggshell calcifications. In controls, however, eggshell calcifications were found in 4 subjects [33].

Potential pitfalls of assessment: eggshell calcifications and non-diagnostic FNA

Anderson et al. [34] investigated ultrasound features in nodules with non-diagnostic FNA results in 393 subjects with single nodules. In terms of eggshell calcifications, they appeared in 9 lesions, but no association with malignancy was found [34].

Factors influencing malignancy risk assessment concerning eggshell calcifications

The retrospective study of Kim et al. [35] focused on eggshell calcifications and included 92 subjects with 93 nodules with eggshell calcifications who underwent thyroid surgery. Sonographic features that had a high sensitivity for malignancy in these patients were the presence of the halo (sensitivity of 62.7%) and disrupted calcification rim (sensitivity of 76.3%) [35]. Regarding malignancy risk detection, Ha et al. [25] found that the positive predictive value of peripheral or eggshell calcification was increased by being combined with high suspicion TIRADS from 33.3% to 66.7-80% [25].

DISCUSSION

Eggshell calcification in a thyroid nodule was described as early as 1976 in a patient with mixed papillary and follicular carcinoma [36], while the first case of a thyroid nodule with eggshell calcification on ultrasonography was reported in 1978 by Gooding [37]. Since then, thyroid ultrasound progressed, but data regarding eggshell calcifications remains scarce. The number of studies providing information regarding eggshell calcifications of thyroid nodules is relatively small when compared to the large volume of data that is published in the specific fields of thyroid ultrasound, FNA, and post-operatory pathological reports. Concerning the specific histological profile amid thyroid malignancies, we discuss the following highlights.

Table 1: Main findings regarding thyroid nodules with eggshell calcifications according to our methods of research, including the PICO analysis [22-35]

First Author/ Publication year/ Reference number **Study design Studied population *P (patients)***	**Positive diagnosis method *I (intervention)***	**Nodules *C (comparison)***	**Main findings *O (outcome)***
Wang/ 2022/[24] Retrospective analysis N=950 subjects (208 males and 742 females) Mean age: 47.0±12 y N=527 patients with papillary carcinoma	surgery	N=1113 Mean size=13.8±9.9 mm Benign: N=486 Malignant: N=627, out of which 527 had aggressive behavior	Eggshell calcifications were a protective factor for papillary carcinoma (OR=0.208, CI=0.049–0.886, p=0.034) Eggshell calcifications were not independent risk factors for aggressive behavior in papillary carcinoma
Yin/2020/[31] Retrospective N=543 Mean age: 49.3±13.2 y	surgery	N=543 Benign: N1=210 (38.67%), out of which 177 adenomas Malignant: N2=333 (61.32%) Macro-calcifications in 204 (37.6%)	Eggshell-in-a-row calcifications were more frequent in benign nodules (1.7% vs. 0.6%, p<0.01) Eggshell discontinuous calcifications were more frequent in malignant nodules (2.2% vs. 0.6%, p<0.01) In benign nodules (N=210): eggshell in a row calcifications N=9 (only adenomas - 7.69%) eggshell discontinuous calcifications N=3 (only adenomas - 2.56%) In malignant nodules: eggshell in a row calcifications, in medullary carcinoma N=3/3 eggshell discontinuous calcifications, in papillary carcinoma N=12/312 (3.84%)
Ha/2019/[25] Retrospective N=954 Mean age: 50.8 y (range: 13–86 y)	surgery CNB FNA	N=1112 nodules (≥ 5 mm) Nodules with echogenic foci N=390 Benign: N=136 Malignant: N=254 Nodules with eggshell calcifications N=21	Nodules with eggshell calcifications (N=21) were more frequently benign (66.7% benign vs. 33.3% malignant, p=0.002 In malignant nodules: surgery (N=413) or CNB (N=4) In benign nodules: surgery (N=65), repeated FNA or CNB (N=41), FNA or CNB with no change in size >12 months (N=589)
Kobayashi/2018/[23] Retrospective N=2678 subjects	surgery	N=2902 Nodules with calcifications=747 (26%) Among patients who underwent surgery: papillary carcinoma N=941 diffuse sclerosing variant of papillary carcinoma N=18 cyst-forming type of papillary carcinoma N=32 metastatic lymph nodes from papillary carcinoma 161 nodes follicular carcinoma N=337 undifferentiated carcinoma N=41 medullary carcinoma N=137 primary thyroid lymphoma N=173	Eggshell calcifications were found in: papillary carcinoma N=45/941 (4.78%) metastatic lymph nodes from papillary carcinoma N=2/161 (1.24%) follicular carcinoma N=40/337 (11.86%) undifferentiated carcinoma N=18/41 (43.90%) No eggshell calcifications were found in diffuse sclerosing and cyst-forming variants of papillary carcinoma, medullary carcinoma and primary thyroid lymphoma.

Zayadeen/2016/[30] Retrospective N=1466 patients (1201 female and 265 male, female-to-male ratio=4.75:1 Mean age: 56 y (range: 11–96 y)	FNA (N=1991) and/or surgery (N=376)	N=2002 nodules 348 nodules in male patients (17%) and 1654 nodules (83%) in female patients Malignant: N=148 (7.4%)	Eggshell calcifications in 45 benign lesions (from 1854 confirmed benign nodules = 2.42%) and 11 malignant lesions (from 148 malignant nodules = 7.43%)
Anderson/ 2014/[34] Retrospective N=393 (328 females, 65 males) subjects with single nodules with non-diagnostic FNA Median age: 57 y (range: 12-94 y)	Following non-diagnostic FNA: Repeated FNA and/or surgery and/or US follow-up	N=393 Nodules with eggshell calcifications N=9/393 (2.3%, 95% CI: 1.1%, 4.3%)	Nodules with eggshell calcifications did not associate with malignancy Increases in volume, anteroposterior diameter, mean or minimum diameter were associated with increases in odds of malignancy
Arpaci/2014/[26] Retrospective N=269 subjects (79.9% female) Mean age: 56.9±13.1 y	FNA (N=907) Surgery (N=43)	N=907 Mean diameters: with macro-calcification: 23.92 ± 14.15 mm without macro-calcification: 15.72 ± 7.53 mm Nodules with macro-calcifications were larger ($p < 0.001$)	Benign nodules rates were higher in nodules without eggshell calcifications compared with nodules with eggshell calcifications (80.3% vs. 67.9%, $p=0.036$) Suspicion for malignancy rates was higher in nodules with eggshell calcifications (7.5% vs. 1.9%, $p=0.010$) In nodules with vs. without eggshell calcifications, no statistical significance was found for: malignant and non-diagnostic rates, pathology results in patients who underwent surgery
Lee/2013/[22] Retrospective N=92 (63 females, 29 males)	FNA (N=103)	N=103 After FNA: Benign N=31 Malignant N=69 Non-diagnostic N=3 After histological confirmation/follow-up: Benign N=34 Malignant N=69	No statistically significant association between eggshell calcification and malignancy
Kim/2013/[27] Retrospective N=1078 subjects (171 males and 907 females) who underwent thyroidectomy for nodular disease Mean age: 47.2 ± 11.1 y (range: 16-82 y)	surgery	N=1432 Benign: N=126 Malignant: N=1305	There was no statistically significant association between annular calcifications and malignant or benign nodules Prevalence of annular calcifications in malignant nodules=31/1305 (2.4%) Prevalence of annular calcifications in benign nodules=5/126 (5%)
Cai/2010/[33] Case-control N=27 cases with medullary carcinoma (13 males and 14 females) Mean age: 45.7±12.8 y N=50 controls (5 males and 45 females) Mean age: 47.2±11.6 y	MTC - surgery controls - NA	N=35 Sizes: 2.39±1.22 cm in the medullary cancer group and 2.42±1.00 in controls - a difference not statistically significant	Eggshell calcifications were found only in controls (N=4) Macro-calcifications were more frequent in patients with medullary carcinoma
Anderson/2010/[28] Retrospective N=61 subjects with nodular Hashimoto's thyroiditis (54 females and 7 males) Median age: 49 y (range: 28–87 y)	FNA	N=64 average mean diameter=15.3 ± 7.33 mm average maximum diameter=19.5 ± 10.39 mm average minimum diameter=11.5 ± 5.63 mm	20% (13/64) nodules had calcifications 4.7% (3/64) nodules had eggshell calcifications 23% (3/13) calcifications were eggshell Eggshell calcifications - more frequent in subjects with normal parenchyma

Anderson/2010/[32] Retrospective N=78 subjects with Hashimoto thyroiditis and nodules Subjects with benign nodules: 85% females Median age: 50 y (range: 30–89 y) Subjects with malignant nodules: 92% females Median age: 54 y (range: 35–89 y)	FNA or surgery	N=82 Benign: N1=69 (84%) Malignant: N2=13 (16%) (12 papillary carcinoma and 1 lymphoma)	Eggshell calcifications were present in: 15% of malignant nodules and 1% of benign nodules - the difference was not statistically significant
Kim/2008/[35] Retrospective N=92	surgery	N=93 nodules and eggshell calcification who underwent surgery Benign: N=34 Malignant: N=59 (papillary carcinoma) Sizes from 4 to 50 mm (mean=16 mm), with no statistically significant difference between groups	In nodules with eggshell calcification, the highest sensitivity for malignancy was found in halo (62.7%) and disrupted calcification rim (76.3%)
Yoon/2007/[29] Retrospective N=65 (57 females) no statistically significant difference in age between benign (54.3 ± 12.7 y) and malignant (54.3 ± 12.7 y) groups	FNA (N=44) surgery (N=3) both (N=18)	mean sizes ± SD: benign nodules (N=53): 13 ± 8 mm (range=3–37 mm) malignant nodules (N=9): 14.4 ± 6.8 mm (range=5–28 mm)	No statistically significant difference between benign and malignant groups in terms of the presence and type of peripheral calcifications

Papillary thyroid carcinoma

Papillary carcinoma accounts for the majority of thyroid cancer cases and has increased in prevalence in recent years, mainly through the increased use of diagnosis techniques, including ultrasonography and FNA. Even though its prognostic is usually good, properly identifying cases remains an important link in the management of these patients [38-40]. While the presence of micro-calcifications is a highly suggestive feature and may even predict cervical lymph node metastasis [41], the implications of macro-calcifications such as eggshell calcifications are not so clear until the present time thus their importance for daily practitioners in the field of ultrasound of any type, endocrinology or endocrine surgery as well as primary health care. None of the studies linked eggshell calcifications to a higher risk of malignancy. However, many of them did not reach statistical significance for tested hypotheses [22,26,27,29].

One of the most important findings was provided by Wang et al. [24], who found that eggshell calcifications decreased the risk of papillary carcinoma and did not promote aggressive tumor behavior [24]. Even though data does not link eggshell calcifications with malignancy, they have been reported in patients with papillary carcinoma [23,28]. When assessing a nodule with eggshell calcifications, other characteristics should also be taken into consideration, and the risk of papillary carcinoma, even though small, should not be completely overlooked [42].

Medullary thyroid carcinoma

Medullary type of carcinoma involves ultrasound as the most important preoperative imaging technique, as stated by the ATA 2015 guidelines [43], aiding not only in identifying the solitary nodule but also in investigating lymph node metastases [44]. Usually, nodules appear hypoechoic, with a patchy structure, vascularized, and may have micro- or macro-calcifications [24,45-47].

When analyzing data regarding eggshell calcifications and medullary carcinoma, evidence was scarce, and three studies were included [23,31,33]. Even though the largest one did not find any eggshell calcifications in patients with medullary carcinoma, the study of Yin et al. [31] found these calcifications in all three patients with medullary carcinoma. One important difference between these studies is the fact that Yin et al. [31] included only patients with calcifications, while Cai et al. [33] focused on ultrasound features of medullary carcinoma in general. Even though the study of Cai et al. [33] included more patients with medullary carcinoma (N=27), overall, the study of Yin et al. [31] identified the three medullary carcinoma patients from a larger pool of patients with thyroid nodules and calcifications (N=543) [31,33]. Despite the rarity, it is important to keep in mind that there have been cases of eggshell calcifications in patients with medullary carcinoma so that the diagnosis is not overlooked solely based on this characteristic. Further research is needed to understand the significance of egg-shell calcification in relation to the medullary type of carcinoma.

Follicular thyroid carcinoma

Kobayashi et al. [23] found eggshell calcifications in 11.86% of patients with follicular carcinoma and nodules with calcification [23]. Apart from this large study, eggshell calcifications have also been mentioned in case reports of patients with follicular carcinoma. Cai et al. [48] reported the case of a 67-year-old female who presented with a solitary kidney tumor diagnosed by pathology as follicular thyroid carcinoma. Thyroid ultrasound identified two different foci in the same lobe, and one of the nodules presented eggshell calcification with an incomplete halo [48].

Three more cases of follicular thyroid carcinoma were reported by Lee et al. [49]. Two of the three cases involved 75-year-old females who were diagnosed with bone metastases caused by a follicular type of thyroid cancer. Both patients had single nodules with interrupted eggshell calcifications on ultrasonography. A third case involved a 54-year-old female with hyperthyroidism and a thyroid nodule with interrupted eggshell calcifications classified as benign by FNA two years prior. A second FNA classified the nodule as indeterminate, and following thyroidectomy, the patient was diagnosed with follicular carcinoma [49].

It is important to emphasize that interrupted eggshell calcifications may be a sign of malignancy, as stated by the ETA 2017 guidelines [50]. Moreover, a high TI-RADS score remains important in malignancy detection in patients with eggshell calcifications as well, increasing positive predictive value [25].

Thyroid autoimmune disease

Hashimoto's chronic thyroiditis is the most common autoimmune thyroid disease and the main cause of hypothyroidism in the modern era [51]. It may lead to the development of nodules [52] and it is another thyroid condition where eggshell calcifications can be found with a low prevalence of less than 5% [32]. It is unclear why these calcifications are more frequent in nodular thyroiditis with otherwise normal gland parenchyma.

Another aspect worth mentioning is the association of Hashimoto's thyroiditis with thyroid cancers, including primary thyroid lymphoma and papillary carcinoma [53]. The connection with papillary thyroid cancer, however, is still debated, with some studies finding an increased risk while other studies finding thyroiditis as a protective factor [54-56]. This raises the question of how the presence of calcifications in general and eggshell calcifications in particular should be interpreted in patients confirmed with Hashimoto's thyroiditis based on serum thy-roid antibodies and/or cytological reports. The lack of statistically significant data regarding the prevalence of eggshell calcifications in benign versus malignant nodules requires larger studies to confirm or infirm the hypothesis that in patients with Hashimoto's thyroiditis, eggshell calcifications are more frequent in malignant nodules [28,32].

Further researches

For some thyroid pathologies, evidence regarding eggshell calcifications remains at the case report level. Malignancies previously found in patients with nodules with eggshell calcifications include oncocytic thyroid cancer [57], and primary squamous cell carcinoma [58], a rare tumor with similar behavior to anaplastic carcinoma [59]. Other benign conditions reported include follicular thyroid adenoma [60] and Hürthle cell adenoma [61]. Hürthle cell adenomas and carcinomas are classified as subtypes of follicular neoplasms, despite their distinct molecular pathogenesis [62]. Recently, Hürthle cells have been renamed to oncocytic cells [63]. (Figure 1).

Of note, apart from thyroid disease, when faced with eggshell calcifications, clinicians should also be mindful of diseases in surrounding organs. One such example is the case reported by Ahn et al. of a 36-year-old female who underwent a thyroid ultrasound due to a complaint of a cervical mass [64]. The ultrasound revealed a thyroid mass with eggshell calcification. However, surgery revealed that the mass was an oesophageal tumor, and pathology diagnosed it as a schwannoma [64].

Overall, the identification of calcifications at thyroid ultrasound should be assimilated to the larger frame of malignancy criteria according to the current guidelines in the thyroid field [65-67].

On a larger scale, we mention the fact that calcium deposits represent incidental findings in many medical areas outside the specific thyroid exploration, including other malignancies (at the neck, thorax, and mediastinum), infectious diseases, inflammatory, and autoimmune conditions [68-72].

Figure 1: This is a prior unreported unusual case of eggshell calcifications on an 80-year-old male admitted for enlargement of a prior goiter (that he refused to investigate for more than one decade); due to compressive neck symptoms, total thyroidectomy was done with a good post-surgery outcome; the pathological report showed a follicular adenoma with necrosis and hemorrhage

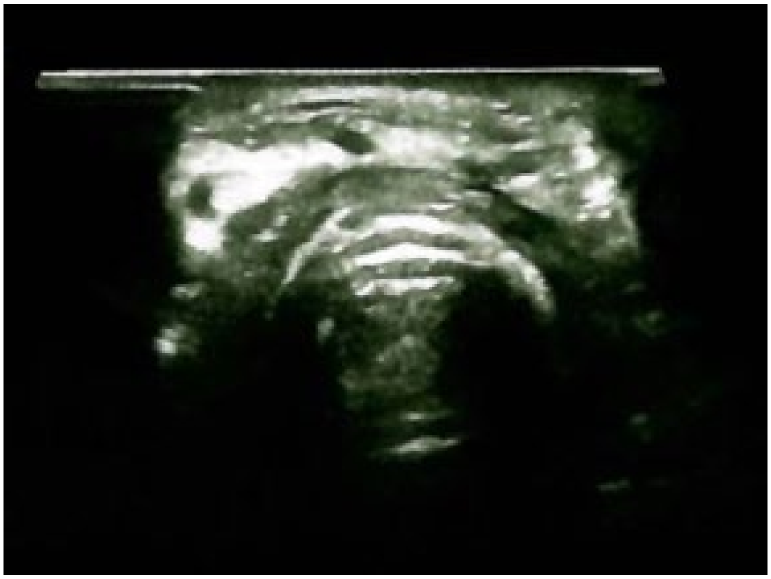
1E. 1-month post-operatory neck ultrasound check-up shows no thyroid remnants



The most common clinical entities associated with eggshell calcification in these mentioned anatomic areas may involve lymphomas, amyloidosis, sarcoidosis, tuberculosis, scleroderma, etc. [73,74]. Another pathogenic trait of calcifications includes calcium and phosphorus anomalies of signal transduction pathways as seen in primary hyperparathyroidism, but, mostly, in chronic renal disease-related tertiary (or secondary) hyperparathyroidism (especially in patients undergoing different types of dialysis) and hypoparathyroidism underlying dysfunction of parathormone and even 25-hydroxyvitamin D regulation [75-77]. Arterial (and generally endothelial) calcifications may be a sign of increased cardiovascular disease in addition to the mentioned anomalies. This might add to a globally increased disease burden leading to a poor outcome [78-82].

CONCLUSIONS

A high TI-RADS score remains important in malignancy prediction while eggshell calcifications might add to the positive predictive value, yet, as a single input this trait is difficult to be classified as a standalone contributor element. Based on these findings, it is safe to say that when faced with eggshell calcifications on thyroid ultrasound, especially if they appear interrupted, clinicians should not rule out the possibility of thyroid carcinoma, as pointed out by our research (Table 1).

Despite the clinical and epidemiological significance, the accurate diagnosis, monitoring of the diagnosed patients, and available licensed treatments remain the challenges of NASH.

Conflicts of interest and sources of funding
The authors declare no conflict of interest.
This research received no external funding

Acknowledgments
We thank the patient and his family. We thank the medical and surgical teams involved in this case. We particularly thank Dr. Anda Dumitrascu for the computed tomography captures.

SYSTEMATIC REVIEW

A Systematic Review of the Influence of Aquatic Exercises on the Physical and Psychological Health of Children with Autism Spectrum Disorder

Tejas P. Ghuntla[1], **Jyoti R. Dholakiya**[2]

Abstract: *Background: Children with Autism Spectrum Disorder (ASD) show significant motor deficits and behavioral dysfunctions, as part of their clinical manifestations. Also, these children are facing important difficulties in social learning, which negatively impacts their adjustment to society's requirements. Apart from other modes of exercise, aquatic exercises may be more attractive to children. Aquatic exercises have been shown to have a beneficial effect on gross motor skills and executive functions in children with ASD. Aim: To study the influence of aquatic exercises on the physical and psychological health of children with ASD. Methods: Researchers used the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines for reporting systematic reviews and meta-analyses. Researchers looked for articles on PubMed, Google Scholar, and by manual search. Searched articles were screened for relevancy. Potential articles were selected using inclusion and exclusion criteria. Results: Out of the 231 articles, four studies were included in the current systematic review. The age of participants ranged from 3−15 years. Overall, included studies found improvements in various aspects of gross motor and executive functions by aquatic exercise in children with ASD. Conclusion: Aquatic exercises can provide health benefits to children with ASD. Aquatic exercises can be useful as a part of therapy in children with ASD. There is wide scope for further studies to evaluate the beneficial effects of aquatic exercises.*

Keywords: *aquatic exercise, autism spectrum disorder, motor skills, cognitive functions*

INTRODUCTION

Autism spectrum disorder (ASD) is characterized by repetitive behaviors, and deficiencies in social and communication skills [1,2,3]. Because of motor deficits, persons with ASD are not involved in social learning experiences to acquire sensory information the same way as others [3,4,5]. Children with ASD often show problems of behavior that negatively impact involvement in the community [6]. Significantly more aggression, inattention, and withdrawal behaviors are shown in children with ASD [6,7]. Self-injurious and stereotypical behaviors are also seen in children with ASD [6].

As movement disorders are seen in ASD [3,4], the goal of physical activity is to control the neural mechanisms that support the acquisition and retention of new skills [3,8]. Exercise programs are useful for improving motor and cognitive skills in children with ASD [3,9,10]. Apart from the other modes of physical exercise, the use of aquatic exercise in children with disabilities is appealing as they are usually not interested in regular physical exercises that may not be attractive to them [3,11,12,13,14,15].

This systematic review evaluates the influence of aquatic exercises on the physical and psychological health of children with ASD. Aquatic exercise's valuable response may provide good hope for therapies in children with ASD.

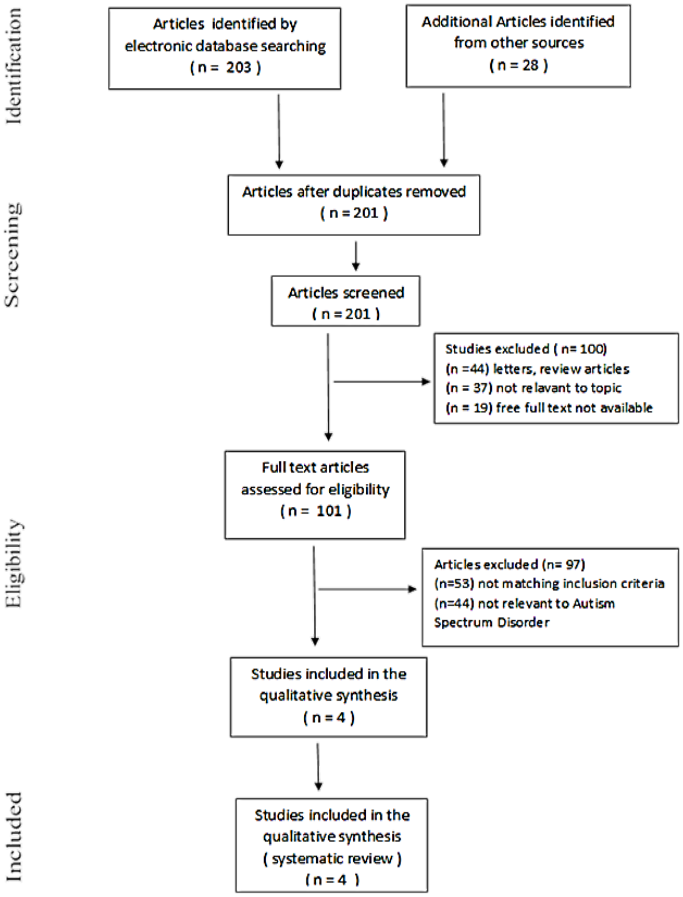
MATERIALS AND METHODS

Researchers used the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines for reporting systematic reviews and meta-analyses (Figure 1) [17].

Search Strategy

Relevant studies were identified by a literature search of the papers published only in English, in electronic databases of Google Scholar and PubMed Central. Words used in the search strategy were “therapeutic effect”, “autism spectrum disorder”, “aquatic exercise”, “motor skill”, “cognitive functions”, “social activities”, and “psychological health”. The search string used for PubMed search is (autism spectrum disorder) AND (aquatic exercises OR aquatic therapy) AND (cognitive functions) AND (motor functions) AND (social activities) AND (psychological health). For the search interval, the start date restriction was not applied, and the end date was kept till the end of 2023. A literature search was also done directly online through Google search. A reference list of filtered studies was also searched to get relevant articles, while the grey literature was not searched.

Figure 1: Flow chart article search and study selection



Identification
Articles identified by electronic database searching (n = 203)
Additional Articles identified from other sources (n = 28)
Screening
Articles after duplicates removed (n = 201)
Articles screened (n = 201)
Studies excluded (n= 100)
(n =44) letters, review articles
(n = 37) not relavant to topic
(n = 19) free full text not available
Eligibility
Full text articles assessed for eligibility (n = 101)
Articles excluded (n= 97)
(n=53) not matching inclusion criteria
(n=44) not relevant to Autism Spectrum Disorder
Studies included in the qualitative synthesis (n = 4)
Included
Studies included in the qualitative synthesis (systematic review) (n = 4)

Studies Selection Criteria

Studies filtered in the primary search were assessed for the following inclusion and exclusion criteria. PICO (an acronym for Population, Intervention, Comparison, Outcome) criteria [18,19,20,21], as described in Table 1, was used to retrieve relevant studies.

Table 1: Search strategy (PICO criteria)

	Definition
Population	Children with ASD
Intervention	Aquatic exercises
Comparison	N/A
Outcome	Assessing physical and psychological health through questionnaires or measurement

Abbreviations: ASD - autism spectrum disorder; N/A- not available; PICO - Population, Intervention, Comparison and Outcome

Inclusion criteria:

- Studies including aquatic exercise
- Studies having participants with ASD
- Studies include the evaluation of the aquatic exercise effects

on participants

Exclusion criteria:
- Articles not relevant to ASD
- Free full-text articles not available of studies
- Type of articles as letters and review articles

Study Quality

Reviewers assessed studies independently for inclusion and exclusion criteria mentioned in the study selection criteria. During the detailed reading of studies, queries regarding inclusion and exclusion were sorted out and finally decided by discussion between the authors.

Data Extraction

Reviewers analyzed selected studies under the following headings: name of the first author with initials, year of publication, brief detail of study population, sample size, age, gender, brief detail of aquatic exercise, and brief detail of outcome measure. Reviewers verified the data, and any discrepancies were addressed by discussion and resolved by consensus between the authors.

Data analysis

We extracted aquatic exercise activities and outcome measures in individual articles. Aquatic exercise activities and outcomes in each individual study were analyzed, and collected data was compared.

RESULTS

Literature search

We found 231 eligible articles by combined electronic database search and manual search. After the removal of 30 duplicated studies, the remaining 201 studies were screened by titles and abstracts. In the screening process, a total of 100 studies were excluded for reasons such as 37 studies were not relevant to the topic, 44 studies were letters or review articles, and a free full article was not available for 19 studies. Full-text articles were assessed for eligibility in the remaining 101 studies after the screening process. In this assessment, a total of 97 studies were excluded because 53 studies did not match the inclusion criteria, and 44 studies were not relevant to ASD. Finally, four articles were identified and included in the qualitative analysis. The flow diagram for the study selection process and the reason for exclusion is displayed in Figure 1.

Description of included studies

A brief description of each eligible four studies [3,6,12,22] is detailed in Table 2. The sample size of eligible 4 studies ranged from 7 to 40 participants. All eligible studies were published between 2016 and 2023. Out of the four eligible included studies, one study [3] has not provided information on participants' gender. All four eligible studies [3,6,12,22] included participants with ASD. The ages of participants ranged from 3 to 15 years. Out of four eligible included studies, one study [22] has not provided information on the inclusion and exclusion criteria of participants.

Table 2: Summary of Characteristics of the included studies

First Author, Year	Brief detail of the study population	Sample Size	Age group (Year)	Gender	Brief detail of aquatic exercise	Brief detail of outcome measure
Alaniz LM [12] (2017)	Participants with ASD were recruited. A swim lesson history was gathered. Inclusion and exclusion criteria are described in the study.	7	3 to 7	Both	The intervention was implemented over 3 phases, with eight 1-hour sessions in each phase. Participants attended 8, 16, or 24 hours of group intervention provided in 1-hour increments, once a week. Aquatic occupational therapy intervention is described in the study.	Single-group pre-test and post-test designs were used. Social skills were calculated using a standardized questionnaire, as described in the study, completed by the caregiver before session 1 and again after session 8, session 16, and session 24.
Adin E [22] (2023)	15 individuals with autism, 8 of which were in the experimental group and 7 in the control group, participated in the study	15	10 to12	Both	The experimental group was subjected to swimming exercise for 1 hour, 3 days a week, for 6 weeks. The control group was not included in this exercise.	The respiratory functions and respiratory muscle strength measurements of the subjects were taken 1 day before and 1 day after the 6-week training program. The same pretest–post-test period was applied to the control group.
Faraji S [3] (2023)	40 participants with ASD were recruited and then randomly assigned to a response-oriented aquatic exercise group	40	7 to 10	-----	The response-oriented aquatic group participated in an aquatic program for 8 weeks, three times weekly, for 45 minutes each session at an indoor pool. The control group participants were requested	The pre-and post-test designs were used. Motor skills and executive function were assessed in both groups as described in the

	(n=20) or a control group (n=20). Inclusion and exclusion criteria are described in the study.				not to alter their physical activity patterns for the duration of the study. The control group maintained their daily activities and did not change their physical activities during the intervention.	study, before and after the intervention.
Kanupka JW [6] (2016)	Children with ASD were selected. Inclusion and exclusion criteria are described in the study.	13	3 to 15	Both	The aquatic exercise program was conducted for 1 hour, 1 day per week for 6 weeks. The exercise program consisted of a 10-minute warm-up, a 10-minute strengthening program, 15 minutes of games, a 15-minute free swim, and a 10-minute cool-down, which were all completed in the pool.	Outcome measures as described in the study assessed before and after completion of the aquatic exercise program.

ASD – Autism Spectrum Disorder

In the study by Alaniz LM [12], “social skills” were calculated using the Social Skills Improvement System (SSIS) [23], a 79-item standardized questionnaire completed by the caregiver before session 1 and again after session 8, 16, and 24. The SSIS [23] assesses social skills like cooperation, communication, assertion, empathy, responsibility, engagement, and self-control and problem behaviors like bullying, externalizing, internalizing, hyperactivity/ inattention, and autism spectrum symptoms [12].

In the study by Adin E [22], forced vital capacity measurement, Vital capacity measurement, Breath inspiratory flow, and peak expiratory flow calculation were used.

In the study by Faraji S [3], The Bruininks-Oseretsky Test of Motor Proficiency – Second Edition (BOTMP-2) Short Form [24] was used. This instrument uses 8 subscales, including 14 separate parts, to comprehensively measure motor skills. Four subtests measure fine motor competence: 1) fine motor precision (FMP), 2) fine motor integration (FMI), 3) manual dexterity (MD), and 4) bilateral coordination (BC), and four subtests assess gross motor competence: 1) balance, 2) running speed and agility (RSA), 3) upper-limb coordination (ULC), and 4) strength [3,10,24]. In the study by Faraji S [3], to assess executive function, the computer version of the Wisconsin Card Sorting Test (WCST) was used [25]. This comprises 4 stimulus cards and 128 response cards [3,25].

In the study by Kanupka JW [6], outcome measures included The Pervasive Developmental Disorder Behaviour Inventory (PDDBI) [26] and the Intervention Rating Profile (IRP-15) [27,28,29,30]. The PDDBI is a rating scale designed to assess responsiveness to intervention in children diagnosed with one of the Pervasive Developmental Disorders (PDD) [6,26]. PDDBI subdomains are Sensory/Perceptual Approach Behaviours, Ritualism/Resistance to Change, Social Pragmatic Problems, Semantic/Pragmatic Problems, Arousal Regulation Problems, Specific Fears, Aggressiveness, Social Approach Behaviours, Expressive Language, Learning, Memory, and Receptive language [6,26]. The IRP-15 [6,27,28,29,30] was used to assess the social validity of aquatic exercise as an intervention to improve behavior in children with ASD [6]. One parent of each of the 13 participants reported on the social validity of aquatic exercise as an intervention for their children using a modified version of the IRP – 15 [6,27,28,29,30]. Parents in the study by Kanupka JW [6] rated their opinions of the effectiveness of the aquatic exercise program on a 15-question 6-point scale ranging from 1 (strongly disagree) to 6 (strongly agree), with total scores ranging from 15 to 90 and higher scores indicating greater acceptability [27,28,29,30]. A total score on the IRP - 15 greater than 52.5 indicates that the intervention is acceptable [6,27,28,29,30].

Outcome

All included studies used pre and post-test designs. Alaniz LM [12] observed significant improvement in the overall swim skills score. When examining individual swim skills, the participants advanced most consistently with breath control [12]. At all three time points, the participants, on average, significantly increased their breath control score compared to that of the pre-evaluation [12]. The changing position skill demonstrated significant improvement at 16 and 24 hours [12]. Propulsion skills improved after 24 hours of intervention only [12]. Navigation, exiting the pool, and back float skills did not improve significantly as measured on the Aquatic Skills Checklist (ASC). [12]. Alaniz LM [12] reported analysis of the Social Skills Improvement System (SSIS) [23] scores from baseline to 8 hours of intervention revealed no significant difference in social skills. There was a high rate of noncompliance for completion of the SSIS [23] after 16 and 24 hours of intervention, which prevented statistical analysis of the data [12].

Adin E [22] observed a significant difference between the pre- and post-test in the forced vital capacity (FVC) and forced expiratory volume (FEV1) values of the experimental group. There was no significant difference between the pre-test and post-test in the FVC and FEV1 values of the control group.

The results of the study by Faraji S [3] demonstrated improvements in gross motor skills and executive function following 8 weeks of response-oriented aquatic exercise. Faraji S [3] showed significant differences between re-sponse-oriented aquatic exercise and control groups in receiving, throwing, static balance, dynamic balance, correct responses, conceptual responses, and perseverative errors. A significant difference was observed in the study [3] between response-oriented aquatic exercise groups and control groups from pre- to post-test in bilateral coordination (BC).

In the study by Kanupka JW [6], there was a statistically significant difference in the scores for pre-arousal and post-arousal while there were no other statistically significant differences for pre and post-behavioral subdomains of the PDDBI [6,26]. In the study by Kanupka JW [6], the ratings for all 15 questions on the IRP - 15 ranged from 62 – 90, these scores were all above 52.5, indicating that aquatic exercise is an acceptable intervention for children with ASD [27,28,29,30]. In the study by Kanupka JW,[6], all of the parents agreed the aquatic exercise intervention had a positive effect on their child's behavior (92.3% strongly agree/agree, 7.7% slightly agree), and parents also all indicated that they would be willing to use the intervention again in the future (100% strongly agree) [27,28,29,30].

DISCUSSION

Studies included in the systematic review investigated the effect of aquatic exercises on the physical and psychological health of children with ASD. Overall, included studies found improvements in various aspects of gross motor and executive functions by aquatic exercise in children with ASD.

Studies [3,31,32,33] in the past have shown an improvement in gross motor skills and executive functions with aquatic exercise programs in individuals with ASD. Aquatic exercise may improve arousal levels in children with ASD. [6]. Improved arousal may help children with ASD to learn more efficiently and interact in the aquatic environment [6,16]. A substantial increase in paying attention, tolerating touch, and maintaining eye contact is observed by therapists who have worked with children with ASD in aquatic environments [6,16].

Aquatic therapy may cause complex adaptations of the neuromuscular system and cause improvement in the transmission of neural impulses [3,34]. Aquatic therapy may increase muscle strength by a resistive medium without much pressure on the weight-bearing joints [3,35]. These improvements in executive function in children with ASD could be because of the improvement in activation of the neuron tract and transfer of messages from the brain to the body to perform movement in children with ASD [3,36]. The aquatic environment provides individuals with three-dimensional movements for continuity of movement, which gives more strength to coordination, temporal-spatial knowledge, kinaesthetic perception, and balance [37].

Limitations

In this review, the effect of aquatic exercise on ASD is the primary focus. However, the schedule and duration of the aquatic exercise program module were different among the selected studies. Parameters to measure outcomes were also different among selected studies. As a similar module of the aquatic exercise program is not used in the different studies explored and a similar outcome parameter is not used, it is difficult to generalize the interpretation of the individual studies. Other health problems were not screened for in the study selection criteria. The sample size was also comparatively small in selected studies. No paid tool or utility was used in the assessment of the quality of studies at any stage, which may increase the risk of bias. Another limitation of the search strategy was the English language, and articles that were not freely available also decreased the number of reviewed articles. The selection of articles was done by using only a pre-defined set of electronic databases. Therefore, studies of other electronic databases, which were not included in the search strategy, may contain relevant articles for the topic of this review.

Recommendations for future research

For a more specific evaluation of the positive effects, future research should focus on specific health benefits of aquatic exercise in individuals with ASD. Research should be done using a comparatively large sample size, proper methodology, and standardized outcome measures.

CONCLUSIONS

The present review focused on the effect of aquatic exercises on the health of individuals with ASD. Overall, included studies found beneficial effects of aquatic exercise in individuals with ASD. Further research is required to explore the long-term effects of aquatic exercise and to explore effects with optimal frequency and duration of sessions. However, the role of aquatic exercise seems promising in ASD, but before utilizing it in practice and treatment, properly designed studies are required to examine these effects in more detail, with adequate specificity and accuracy.

Abstract: *Background: Automated data processing is creating and implementing technology that automatically processes data. This computer tool is recommended for doctors because it supports their everyday work, assists in medical diagnosis, and enhances patient care. The aim of this paper is to propose an informatic tool that can extract the values of some parameters of interest from blood test sheets in order to get medical alerts and to monitor the chronic disease. Methods: An application, written in Python, was developed Results: The computer tool extracted automatically the values of glucose, triglycerides, HDL-cholesterol, total cholesterol, and LDL-cholesterol from medical sheets (text-based file or graphic file, respectively), and saved them in a database, accessed and represented in a graphic form the most recent values of these parameters; alerts according to metabolic syndrome criteria and Framingham risk score were generated. Conclusions: This tool contributes to the management of the medical process, saving precious time and helping the doctor in detecting current or future health problems.*

Keywords: *process automation in medicine; Python; medical alerts; metabolic syndrome; Framingham risk score*

INTRODUCTION

Process automation is defined as using software and technologies to automate business processes and functions to accomplish well-defined organizational goals. Automated data processing is creating and implementing technology that automatically processes data [1].

Automated systems, meant to emulate human cognitive capabilities, deploy supervised applications to perform repetitive tasks more accurately and efficiently, saving time and effort for high-volume workloads. In medicine, artificial intelligence has become a valuable tool for improving patient outcomes, particularly in diagnostics, by extracting information from image and text-based files [2].

Chronic patients are followed for years and the disease is monitored according to the clinical status and certain biological parameters. Therefore the medical data about them, saved and quickly accessed, can be of real use in the medical act.

Physicians consult many patients daily, being busy, apart from the actual medical act, with other tasks (electronic filling in of various data, issuing prescriptions, administrative work). Due to the relatively limited time allocated to a consultation, doctors can benefit, using this IT tool, from real support in their work.

Although the computer tool we propose was originally intended for family doctors, specialist doctors can successfully use it (by activating medical alerts, depending on the specialty), especially for chronic patients who return for regular consultations.

The aim of our application is the automation of the medical act, as follows:

- extracting (reading) automatically the values of some parameters of interest from blood test sheets (text-based pdf file or graphic file format);

- saving the blood values and anthropometric parameters for a patient in a database;

- activating medical alerts;

- monitoring the disease by displaying, in a graphic format (chart), the most recent values of the interest parameters**.**

MATERIALS AND METHODS

In this version, the application generates alerts according to metabolic syndrome and Framingham risk score.

Nowadays, the well-established term ‘metabolic syndrome’ (MetS) remains the most useful and widely accepted description of this cluster of metabolically related cardiovascular risk factors, which also predict a high risk of developing diabetes [3].

Many expert groups have attempted to develop a unifying definition for the MetS. We focus, in this paper, on the NCEP ATPIII and IDF criteria.

The NCEP ATPIII (National Cholesterol Education Program - Adult Treatment Panel III) criterion establishes that meta-bolic syndrome is present if three or more of the following five risk factors [3,4]:

• raised triglycerides level: ≥ 1.7 mmol/l (150 mg/ dl);

• reduced HDL-cholesterol: < 1.03 mmol/l (40 mg/dl) in males and < 1.29 mmol/l (50 mg/dl) in females (or specific treatment for these lipid abnormalities);

• raised blood pressure (systolic BP ≥ 130 or diastolic BP ≥ 85 mmHg) (or treatment of previously diagnosed hypertension);

• raised fasting plasma glucose ≥ 5.6 mmol/l (100 mg/dl);

• raised waist circumference >102 cm for men and >88 cm for women.

The new definition given by the International Diabetes Federation (IDF) says that for a person to be defined as having the MetS, he/she must have central obesity plus any two of four additional factors [3]:

• raised triglycerides level: ≥ 1.7 mmol/l (150 mg/ dl);

• reduced HDL-cholesterol: < 1.03 mmol/l (40 mg/dl) in males and < 1.29 mmol/l (50 mg/dl) in females (or specific treatment for these lipid abnormalities);

• raised blood pressure (systolic BP ≥ 130 or diastolic BP ≥ 85 mmHg) (or treatment of previously diagnosed hypertension);

• raised fasting plasma glucose ≥ 5.6 mmol/l (100 mg/dl)] (or previously diagnosed type 2 diabetes).

Central obesity is most easily measured by waist circumference with cut-points that are gender and ethnic-group specific. For example, an abnormal waist circumference for European males is ≥ 94 cm and for European females is ≥ 80 cm. The cut-points for central obesity adopted in the USA by the National Institutes of Health clinical guidelines for obesity were 102 cm for men and 88 cm for women. An abnormal waist circumference for South Asians and Chinese males is ≥ 94 cm and for South Asians and Chinese females is ≥ 80 cm [3,4].

Framingham Risk Score (FRS) and estimation of 10-year Cardiovascular Disease (CVD) Risk is an algorithm adapted from Canadian Cardiovascular Society/Canadian guidelines [5-7].

The PREDATORR (PREvalence of DiAbeTes mellitus, prediabetes, overweight, Obesity, dyslipidemia, hyperuricemia, and chronic kidney disease in Romania) study shows that the prevalence of diabetes mellitus was 11.6% and of prediabetes was 16.5% in the Romanian population aged 20-79 years [8].

The increased risk for cardiovascular disease in prediabetes is multifactorial, with etiologies including insulin resistance, hyperglycemia, dyslipidemia, hypertension, systemic inflammation, and oxidative stress. The preferred treatment is intensive lifestyle management and aggressive pharmacologic therapies directed toward individual coronary heart disease risk factors [9].

The early diagnosis and screening of prediabetes are essential steps toward the prevention of diabetes and associated complications. The American Diabetes Association (ADA) recommends screening adults over 45 years old without known diabetes every 3 years [10].

The Unified Modeling Language (UML) is a general-purpose visual modeling language that is used to specify, visualize, construct, and document the artifacts of a software system. It captures decisions and understanding about systems that must be constructed [11].

Because of its high level of functionality, Python language is used for web development, data science and data analysis, machine learning, startups, and the finance industry, among others [12].

Our application, written in Python, can be schematically described in Unified Modeling Language, using a use-case diagram (Figure 1), which explains the system's static structure, and an activity diagram (Figure 2), which captures information about the system's dynamic behavior.

As one can see in the above diagrams, the application allows, in a successful scenario:

- automatic reading (extracting) (details are given in Result section) from a text-based pdf file, the values of the parameters required for the metabolic syndrome algorithms (ATP III and IDF), respectively, the Framingham score calculation algorithm;
- automatic reading, from a graphic file (tif) (details are given in the “Results” section), of the values of the parameters required for the metabolic syndrome algorithms (ATP III and IDF), respectively, the Framingham score calculation algorithm;
- generating medical alerts;
- saving the values of parameters in the database;
- displaying charts showing the evolution (the last 3 or less, if the patient hasn’t 3 medical tests yet) of the parameters, each graph showing one parameter.

Suppose the patient does not present himself/herself with any analysis sheet. In that case, the application does not read any parameters and displays the chart showing the evolution of the medical parameters from the previous blood tests. The application also highlights the parameters from the most recent test, which were not within normal limits.

In the current version of the application, the database, created in SQLite 3, contains a single table, called Patient, which has the following structure:

- ID (INT, PRIMARY KEY, NOT NULL) – as the primary key;
- CNP (CHAR(13), NOT NULL) – as personal identification number;
- NAME (TEXT, NOT NULL);
- DT (TIMESTAMP) – as the date and time of analysis collection
- G (REAL) – as fasting glucose (or glycemia), expressed in mg/dl
- TG (REAL) as triglycerides, expressed in mg/dl
- HDL (REAL) – as HDL-Cholesterol, expressed in mg/dl
- WC (INT) - as waist circumference, expressed in cm
- COL (REAL) – as total cholesterol, expressed in mg/dl
- LDL (REAL) – as LDL-Cholesterol, expressed in mg/dl;
- SBP (INT) – as Systolic Blood Pressure, expressed in mm Hg;
- DBP(INT) – as Diastolic Blood Pressure, expressed in mm Hg.

There are situations where the scenario is unsuccessful due to automatic data reading errors (or the absence of some parameters from the analysis sheet), but a message will be displayed in this case. Also, the application uses mg/dl, not mmol/l, as the default measurement unit for triglycerides, plasma glucose, HDL-cholesterol, LDL-cholesterol, and total cholesterol, a shortcoming that will be fixed in future versions of the application.

RESULTS

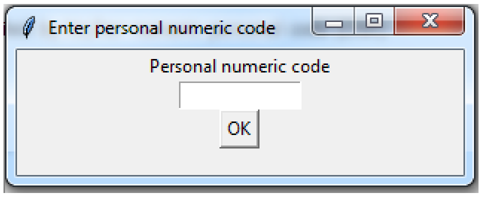
Launching the application

The doctor can launch the application by double-clicking on the link when consulting a patient. According to the structure of the application presented in the UML diagrams, there can be several use cases of the application, discussed below.

The patient has no new medical tests

The identification of the patient using the personal numerical code is performed in all cases. The medic is asked to complete this information. The personal numeric code is programmatically validated (text should contain 13 digits and no other character):

Figure 3: Identify the patient



The program will display a chart with the three most recent values for each medical parameter involved in the metabolic syndrome (for example, HDL is displayed in Figure 4), so the doctor can remember the patient's condition. The application automatically retrieves and displays the parameters and their values for the last test made by the patient and programmatically highlights the abnormal values (Figure 5).

Figure 4: Evolution of HDL (the three most recent values) for a patient. The red line indicates the threshold value of the parameter (in this case, all values below 40, being a man, are abnormal)

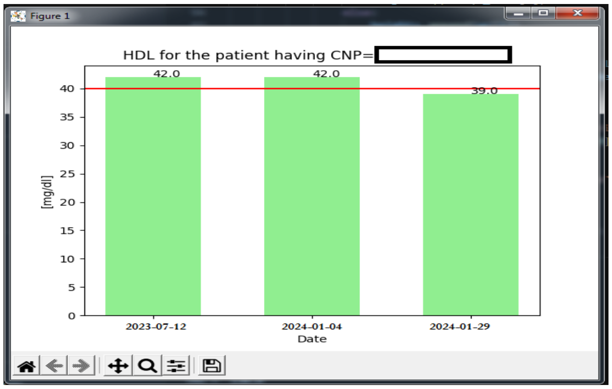


Figure 5: The values from the most recent test

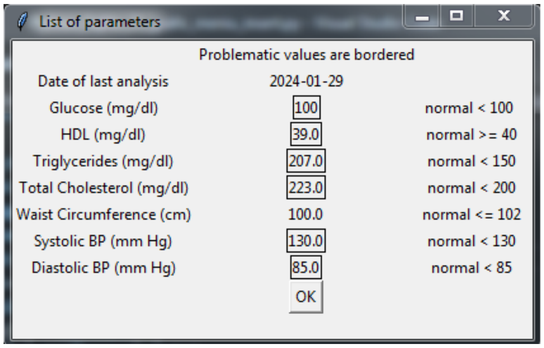


Problematic values are bordered

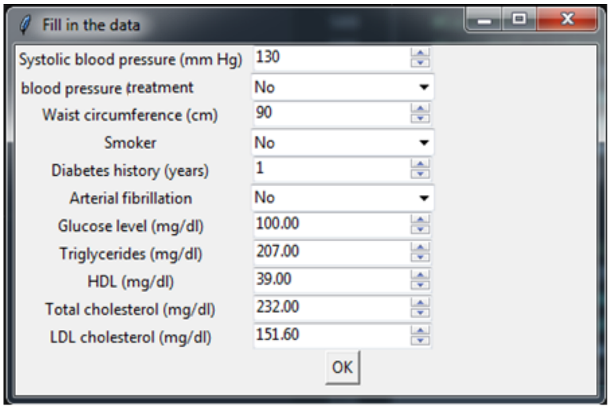
Date of last analysis	2024-01-29	
Glucose (mg/dl)	100	normal < 100
HDL (mg/dl)	39.0	normal >= 40
Triglycerides (mg/dl)	207.0	normal < 150
Total Cholesterol (mg/dl)	223.0	normal < 200
Waist Circumference (cm)	100.0	normal <= 102
Systolic BP (mm Hg)	130.0	normal < 130
Diastolic BP (mm Hg)	85.0	normal < 85

The patient has a new pdf text-based medical test

The program automatically reads (extracts) values of glucose level, triglycerides, HDL, total cholesterol, and LDL cholesterol from a medical test containing more than 20 parameters. We imported the <PyPDF2> module [13], which allows dividing the document into pages. The requested parameters and their corresponding values were searched on each page, using regular expression facilities (after importing the <re> module [14]).

The doctor will validate the automatically read values (Glucose level, Triglycerides, HDL, Total cholesterol, LDL cholesterol) and fill in other values (Systolic blood pressure, blood pressure treatment, Waist circumference, Smoker status, Diabetes history, and presence of Arterial fibrillation) which appear in the window with default values (shown in Figure 6).

Figure 6: The window for validating the read values and for introducing the other requested values. The first six top parameters have default values, the bottom five parameters have the values programmatically extract from the docu-ment



Systolic blood pressure (mm Hg)	130
blood pressure treatment	No
Waist circumference (cm)	90
Smoker	No
Diabetes history (years)	1
Arterial fibrillation	No
Glucose level (mg/dl)	100.00
Triglycerides (mg/dl)	207.00
HDL (mg/dl)	39.00
Total cholesterol (mg/dl)	232.00
LDL cholesterol (mg/dl)	151.60

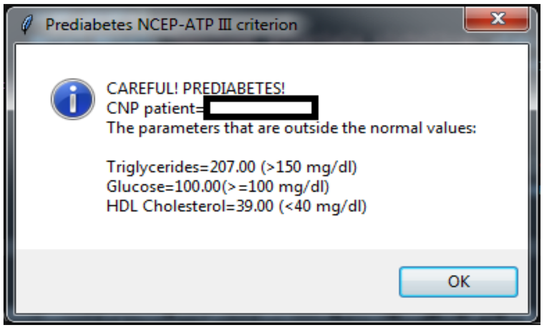
After validating and completing the data, the values corresponding to the columns in the database are saved as a new record in the database, considering the analysis date as the current date, obtained from the system.

An alert regarding the presence or absence of prediabetes is displayed, as in Figure 7 (Prediabetes according to NCEP-ATP III criterion) and Figure 8 (Prediabetes according to IDF criterion). We observe the differences between the two criteria.

The Framingham score is displayed in Figure 9.

In the final step, charts are displayed with the most three recent values of each parameter, including the one from the control day. For example, in Figure 10, the evolution of glucose level is shown (the red line being the threshold value).

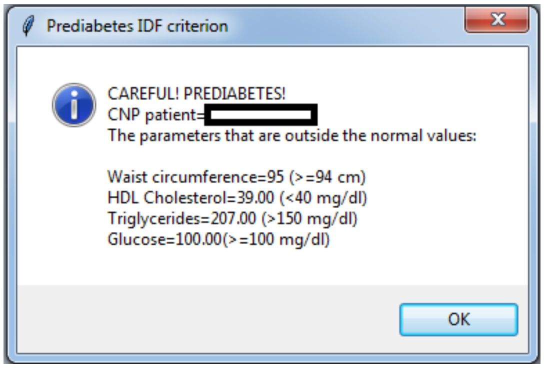
Figure 7: Prediabetes alert according to NCEP ATP III criterion



```
CAREFUL! PREDIABETES!
CNP patient=[redacted]
The parameters that are outside the normal values:

Triglycerides=207.00 (>150 mg/dl)
Glucose=100.00(>=100 mg/dl)
HDL Cholesterol=39.00 (<40 mg/dl)
```

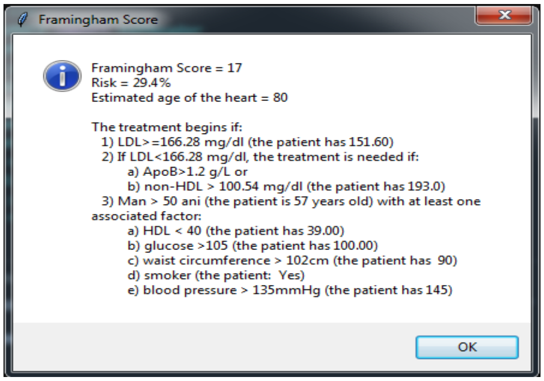
Figure 8: Prediabetes alert according to IDF criterion



```
CAREFUL! PREDIABETES!
CNP patient=[redacted]
The parameters that are outside the normal values:

Waist circumference=95 (>=94 cm)
HDL Cholesterol=39.00 (<40 mg/dl)
Triglycerides=207.00 (>150 mg/dl)
Glucose=100.00(>=100 mg/dl)
```

Figure 9: Cardiovascular disease risk alert according to Framingham score



```
Framingham Score = 17
Risk = 29.4%
Estimated age of the heart = 80

The treatment begins if:
  1) LDL>=166.28 mg/dl (the patient has 151.60)
  2) If LDL<166.28 mg/dl, the treatment is needed if:
        a) ApoB>1.2 g/L or
        b) non-HDL > 100.54 mg/dl (the patient has 193.0)
  3) Man > 50 ani (the patient is 57 years old) with at least one
associated factor:
        a) HDL < 40 (the patient has 39.00)
        b) glucose >105 (the patient has 100.00)
        c) waist circumference > 102cm (the patient has  90)
        d) smoker (the patient:  Yes)
        e) blood pressure > 135mmHg (the patient has 145)
```

The patient has a new medical test in graphic format

The program automatically reads values of plasma glucose, triglycerides, HDL-cholesterol, total cholesterol and LDL-cholesterol. We use pytesseract [15], PIL [16] and cv2 [17,18, 19] modules for corrections and extracting requested values. As shown in the activity diagram, the following steps, in this case, coincide with those from the previous subsection, therefore, everything presented above and illustrated by Figures 7, 8, 9, 10 is also valid here.

Situations in which the application does not offer a successful scenario

If a parameter is missing or an error occurs during the automatic reading, a window indicating the missing parameter is displayed (Figure 11), and the medical alert cannot be generated correctly (for example, for the lack of HDL, the prediabetes alert cannot be generated – Figure 12).

Figure 10: Glucose values for the three most recent blood tests

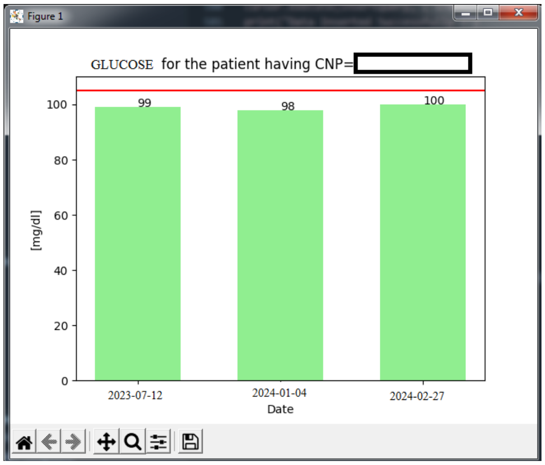


Figure 11: The window indicating a missing parameter

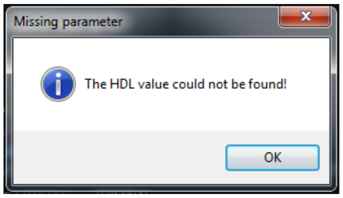
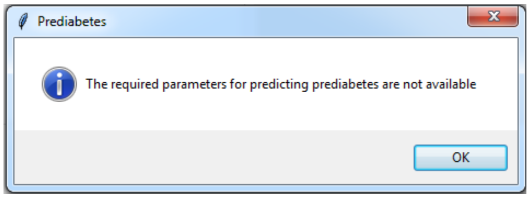


The HDL value could not be found!

Figure 12: The window indicating that the alert could not be generated



The required parameters for predicting prediabetes are not available

DISCUSSION

In this version, the application automatically generates medical alerts according to metabolic syndrome criteria and the Framingham risk score.

Because risk scores, such as the Framingham Risk Score, indicate the patient’s cardiovascular risk for the next ten years, they are very useful. To apply an algorithm classically, the doctor manually uploads the patient's data in the fields related to the algorithm and this procedure takes time. Also, the dynamic verification of the biological values requires a search of the old documents and this is another task that consumes time. This application resolves these medical objectives at once. Therefore, an advantage of the application is that it saves precious time by automatically reading the values of some blood parameters (Figure 6). The values that are not correctly read by the application will be filled in by the doctor.

In Figure 4 and Figure 10, the charts for monitoring the serum HDLc and glucose values are shown. This IT tool can be adapted (extended) depending on the medical specialty. For example, in rheumatology, monitoring can be done by inflammatory markers (C reactive protein, fibrinogen; in endocrinology, the thyroid function can be monitored by TSH values, and in diabetes, the monitoring can be based on HbA1c values. The examples can go on. Therefore, the application is versatile because it can extract any parameter of interest, depending on the medical specialty.

Medical alerts are generated (Figures 7, 8, 9), indicating, in this case, current (metabolic syndrome) or future problems (Framingham risk score).

If the application, in future versions, will access only blood parameters in order to generate medical alerts, the doctor will not have to fill in the window (Figure 6) any other values (such as, in the present case, systolic blood pressure, waist circumference, etc.) than those automatically extracted, thus saving more time.

The limits of the application refer to errors in the automatic process of reading the values, and to the fact that the application uses as measurement unit mg/dl, not mmol/l (for plasma glucose, triglycerides, HDL-cholesterol, LDL-cholesterol, and total cholesterol). The application also presumes that the patients are European (when taking into account waist circumference). These shortcomings will be fixed in a future version of the application, in which the measurement units will be automatically read from the sheets and the application will take into account the patient's race (including a field in the database).

The current version of the application uses classical algorithms, based on medical guides, but it can also use machine learning and deep learning algorithms for prediction.

CONCLUSIONS

This application, despite some problems that could appear when reading the data automatically, can improve the medical activity of a doctor, making his/her work more efficient and saving valuable time through the automation processes it proposes.

The application offers quick access to the parameters involved in a disease, displaying them in charts that illustrate the evolution of the patient's state of health; in this way, the doctor does not rely on information about what the patient remembers from previous visits or on the papers that the doctor has to look for, but on data stored in the database.

The application automatically activates alerts that can help the doctor in diagnosis. Disease prevention measures can also be recommended by the doctor, based on these alerts.

The application is original and can be easily installed. It is scalable because new facilities can be added. However, the number of medical alerts raised by the application must not be excessively high because instead of helping the doctor's work, it can make it more difficult.

This application is intended to be a support tool and not a substitute for the doctor's work. The collaboration between doctors and computer scientists opens new ways of approaching the medical act.

Abstract: *Given the rigorous demands of aerial operations on the human body, this study aims to investigate the body composition differences among aircrew specialties, specifically between medical personnel and mechanics within the Air Force. By examining key body composition metrics such as fat mass, lean mass, and body water, the study seeks to uncover how these variables correlate with aircrew members' distinct occupational duties and overall health. Initial findings indicate subtle but significant body composition variations between groups, suggesting occupational roles may influence physical attributes. There were small differences in body composition between mechanics and medical personnel, primarily based on a greater body mass index, weight, body water, skeletal muscle mass, soft lean mass, and fat-free mass of the mechanics. Body composition analysis by segments suggest a better muscle activation during their duties, but worse nutrition habits in mechanics when compared to medical personnel. This underscores the importance of designing occupation-specific training and nutrition programs to optimize the health and operational performance of aircrew members across specialties.*

Keywords: *aircrew; body composition; nutrition; training; health; performance*

INTRODUCTION

Accurate body composition assessment in military settings is paramount for operational readiness, physical performance, and health outcomes. It emphasized the need for reliable measurement methods within military populations, particularly among Air Force Reserve Officers' Training Corps (ROTC) cadets, highlighting a significant aspect of military fitness assessments, underscoring the necessity of employing accurate and reliable body composition measurement techniques to serve the needs of military personnel better [24]. Other researchers point out the potential adverse effects of unhealthy weight control behaviors, such as weight cycling and disordered eating, prevalent among military personnel [8]. In this line, it was highlighted how body composition is basic to reach operative cardiorespiratory fitness in infantry maneuvers [14]. Additionally, a systematic review and meta-analysis conducted to assess changes in physical performance, body composition, and physical training during military operations revealed significant findings. This study highlighted that deployments could lead to a decrease in endurance performance, among other changes, suggesting the critical role of continuous monitoring and adjustment of training and nutritional strategies to mitigate negative impacts on soldiers' physical conditioning and body composition during deployments [28].

For flight crew members, managing optimal body composition (BC) is crucial due to the unique and stressful nature of their work environment, which includes long durations at high altitudes and irregular working hours that can disrupt sleep patterns and dietary habits [7,13,37]. It is of vital importance to address fatigue among flight crews, especially under extra augmented crew (EAC) schedules implemented during the COVID-19 pandemic, which increases fatigue levels, underscoring the necessity of continuous monitoring and management of crew fatigue to ensure safety and health, suggesting that BC plays a role in maintaining operational efficiency and reducing the risk of fatigue-related errors [19]. It was also found that optimal body composition is critical for pilots, impacting their ability to handle high G-forces and hypoxia at altitude [5,6]. In this line previous authors presented that air force cadets with higher muscle mass and lower fat performed better in G-tests, suggesting that muscle mass improves G-force resistance and cognitive function during flight by enhancing blood flow to the brain [36]. Another important aspect is dysmetria, fact that could negatively impact flight maneuvers, potentially leading to injuries among pilots, showing the necessity to develop specialized training programs aimed at correcting this issue is advisable [10].

Flight crew roles, including pilots, medical staff, and mechanics, are diverse yet integral to ensuring flight safety and efficiency. Pilots helm the aircraft, navigating through various weather conditions and regulatory environments to guarantee a secure journey from start to finish. They communicate with air traffic control and handle emergencies with precision. Medical personnel aboard, such as flight nurses and paramedics, are pivotal in aeromedical transport missions, offering crucial care during emergencies, patient transfers, and providing specialty care mid-flight. Their expertise is indispensable for medical repatriation and in managing healthcare in the unique and stressful conditions of flight. Mechanics and aviation engineers ensure that aircraft are safe and airworthy. Their work involves regular maintenance, pre-flight checks, and addressing any mechanical issues that arise. They are essential for the aircraft's reliability, working behind the scenes to prevent technical failures and ensure that all systems function correctly throughout the flight [20,21].

Understanding body composition standards serves as a foundational step towards enhancing nutritional habits and tailoring training systems to fit the specific realities of individuals, especially those in physically demanding roles such as military personnel. Previous studies emphasize the multifaceted relationship between body composition and military performance, highlighting the diverse implications of BC across various aspects of physical readiness and performance [16]. By recognizing BC benchmarks, individuals and organizations can better design nutritional and training programs that are not only effective but also aligned with the unique demands and realities faced by the individuals. Tailored approaches that consider the specific BC requirements can significantly contribute to improved overall health, fitness, and performance outcomes. This understanding underscores the necessity of integrating comprehensive BC knowledge into the development of personalized nutrition and exercise regimens [7,11]. Therefore, this study aimed to analyze body composition differences between the types of specialty of aircrews, to provide data of their standards, and to improve their preparation for the extra risks they need to face when they are transported in an aircraft. We hypothesized that: i) there would be differences in body composition between specialties, ii) mechanics would have higher values of lean mass and lower values of fat mass than the medical personnel, iii) mechanics would have higher values of fat-free mass in their arms than the medical personnel**.**

MATERIALS AND METHODS

1. Experimental approach to the problem

To implement the body composition assessment, we followed previous procedures [4,9,29] in which the participants stood upright on foot electrodes on the instrument platform, with arms not touching the torso. They were barefooted and without excess clothing. Four-foot electrodes were used, two of which were oval-shaped and two heel-shaped, and prior to testing the skin was cleaned and dried. Participants were asked to grip the palm and thumb electrodes. The system was calibrated before the testing session and the contacting surface of the electrodes was cleaned with alcohol before each measurement. Participants abstained from alcohol consumption and vigorous exercise for 24 hours before the measurement and were measured in the morning after overnight fasting to control hydration status, as in previous research with bioelectrical impedance.

2. Subjects

A randomized cross-sectional experimental study was conducted to analyze body composition differences of aircrews, depending on their specialty. 54 male aircrews were analyzed and classified according to their specialty (mechanics, N = 27, age: M = 43.6, SD = 7.1; medical personnel, N = 27, age: M = 42.2, SD = 11.8) of the Spanish Army with a qualification of “fit” according to the periodic medical examination as recorded in the ministerial order 23/2011. Besides, during the research, they were carrying out the periodic aeromedical training included in the ministerial order 23/2011 and the STANAG 3114 “Aeromedical Training of Flight Personnel” (NATO regulations). Before starting the research, the experimental procedures were explained to all the participants, who gave their voluntary written informed consent under the Declaration of Helsinki. The procedures conducted in the present research were designed and approved by the Medical Service of the Aerospace Medicine Instruction Centre of Spanish Air Forces and the University Ethic Committee (CIPI/18/093).

3. Instruments

A bioimpedance analyzer (InBody 720, Biospace Co. Ltd., Seoul, South Korea) was used for body mass measurement (to the nearest 0.1 kg) and body height (to the nearest 0.1 cm). InBody 720 is a multifrequency impedance body composition analyzer, which uses an eight-point tactile electrode method to take readings from the body. It measures the resistance at five specific frequencies (1 kHz, 50 kHz, 250 kHz, 500 kHz, and 1 MHz) and reactance at three specific frequencies (5 kHz, 50 kHz, and 250 kHz) on each of five segments (right arm, left arm, trunk, right leg, and left leg). Bioelectrical-impedance analysis (BIA) is one of the methods available for measuring body composition in healthy populations. Its simplicity, portability, cost, and subject acceptance make it a very desirable technique. The reliability of BIA compared to the gold standard body composition measurement (Dual-energy X-ray absorptiometry, DXA) has been successfully demonstrated for a wide range of normal and overweight populations [12,33] and military samples [1].

Data were electronically imported to Excel using Lookin'Body 3.0 software. The following parameters were analyzed: i. Body mass (kg), ii. Height (cm), iii. Body Mass Index (BMI) (kg/m2), iv. Total Body Water (TBW) (kg) (including left and right arms, trunk, and left and right legs), v. Intracellular Water (ICW) (l) (including left and right arms, trunk, and left and right legs), vi. Extracellular Water (ECW) (l) (including left and right arms, trunk, and left and right legs), vii. Proteins (kg), viii. Minerals (kg), ix. Body Fat Mass (BFM) (kg) (including left and right arms, trunk, and left and right legs, in kg and %), x. Percentage of Body Fat (PBF) (%), xi. Soft Lean Mass (SLM) (kg), xii. Fat-Free Mass (FFM) (kg) (including left and right arms, trunk, and left and right legs, in kg and %), xiii. Skeletal Muscle Mass (kg).

4. Statistical analysis

The SPSS statistical package (version 21.0; SPSS, Inc. Chicago, Illinois) was used to analyze the data. Normality assumptions were checked with a Shapiro-Wilk test for all the subgroups. Specialty differences were analyzed with a T-Student test for parametric samples and a Mann-Whitney test for no parametric samples. Homoscedasticity was tested with the Levene test. The level of significance for all the comparisons was set at $P \leq 0.05$.

RESULTS

The results are reported with their mean and standard deviation. Table 1 shows the results of body composition. No significant differences were found for the effect of type of work. There was a small effect of the specialty (mechanics had higher values than the medical personnel) in body mass (84.3 kg vs 81.1 kg), BMI (27.1 kg/m^2 vs 25.8 kg/m^2), TBW (46.9 l vs 45.7 l), ICW (29.4 l vs 28.6 l), proteins (12.7 kg vs 12.3 kg), SLM (60.4 kg vs 58.8 kg), SMM (36.4 kg vs 35.2 kg), FFM (64.1 kg vs 62.5 kg).

Table 1: Results of body composition variables by specialty groups

ICW (l)	28.6	3.42	29.4	3.39	-0.906	0.369	-0.247
ECW (l)	17.1	2.01	17.5	2.14	-0.608	0.546	-0.166
Proteins (kg)	12.3	1.48	12.7	1.45	-0.860	0.394	-0.234
Minerals (kg)	4.36	0.49	4.44	0.55	-0.609	0.545	-0.166
BFM (kg)	18.6	11.0	20.1	7.74	-0.612	0.543	-0.167
PBF (%)	21.7	9.27	23.3	6.28	-0.701	0.486	-0.191
SLM (kg)	58.8	6.97	60.4	7.06	-0.810	0.421	-0.221
FFM (kg)	62.5	7.37	64.1	7.50	-0.803	0.426	-0.219
SMM (kg)	35.2	4.46	36.4	4.44	-0.920	0.362	-0.250

Note. M = Mean; SD = Standard Deviation; t = t-test; BMI = Body Mass Index; TBW = Total Body Water; ICW = Intracellular Water; ECW = Extracellular Water; BFM = Body Fat Mass; PBF = Percentage of Body Fat; SLM = Soft Lean Mass; FFM = Fat Free Mass; SMM = Skeletal Muscle Mass

Table 2 shows the results of FFM and BFM by body segments. No significant differences were found for the effect of specialty. There was a small effect of the specialty (mechanics had higher values than the medical personnel) in the fat-free mass of the right arm (3.75 kg vs 3.58 kg), the fat-free mass of the left arm (3.69 kg vs 3.53 kg), the fat-free mass of the trunk (28.6 kg vs 27.7 kg), and the body fat mass of the trunk (10.9 kg vs 9.75 kg).

Table 3 shows the results of body water (total, intracellular and extracellular) by body segments. No significant differences were found for the effect of type of work. There was a small effect of the specialty (mechanics had higher values than the medical personnel) in the total body water of the right arm (2.92 l vs 2.78 l), the left arm (2.87 l vs 2.84 l), and the trunk (22.2 l vs 21.5 l). There was a small effect of the specialty (mechanics had higher values than the medical personnel) in the intracellular water of the right arm (1.82 l vs 1.74 l), the left arm (1.79 l vs 1.71 l), and the trunk (13.9 l vs 13.4 l). There was a small effect of the specialty (mechanics had higher values than the medical personnel) in the extra-cellular water of the right arm (1.09 l vs 1.04 l), the left arm (1.08 l vs 1.03 l), and the trunk (8.31 l vs 8.09 l).

Table 2: Results of body composition variables by specialty groups

	Medical personnel		Mechanics		Specialty effect		
	M	SD	M	SD	t	p	Cohen's d
FFM Right Arm (kg)	3.58	0.61	3.75	0.57	-1.052	0.298	-0.286

DISCUSSION

This study aimed to analyze body composition differences between mechanics and medical personnel of the Air Force. The first hypothesis was partially fulfilled since there were small differences in body composition between specialties. The second hypothesis was partially fulfilled since the effect of the specialty in the results was small. The third hypothesis was partially fulfilled since there were small differences in the fat-free mass between specialties.

Height, body mass and body mass index measures have been traditionally used as a first basic approach to study body composition [2,11]. Although the differences found were small, it is important to note a greater weight and body mass index in the mechanics group. The morphological distribution of the body mass can be more easily identified through the soft lean mass, the skeletal muscle mass, and the fat-free mass [17], which were greater in mechanics. These differences suggest predominant values of lean mass, rather than body fat, in the body mass values of mechanics. Although mechanics are not as responsible as pilots in the control of aircraft, their performance is crucial to control and maintain the correct functioning of aircraft devices [23]. Mechanics need to use tools in flight time, and to cope with the vibrations, accelerations, and changes of directions of the aircraft, while they maintain their stance [3,15,25]. These aspects could be crucial in the development of muscle mass groups, especially segmental stabilizers. Muscles are made of water and proteins, and the small differences that were found between specialties (greater in mechanics than in medical personnel) are coherent with the previous results and previous research [4].

The analysis of body composition by segments can provide better insights of which are anatomical regions better involved in the morphological differences between specialties. The fat-free mass was higher in the upper extremities for the mechanics' group, and this aspect reinforces the previous assumptions and descriptions about the different jobs of each specialty. Mechanics usually work with tools that need to be controlled by their hands, involving the muscles of their arms, applying different kind of forces and torques to adjust the devices. Many muscle groups in the trunk are responsible of the stability of the core, that is crucial to maintain the stance in flight time [15,18,38]. It could be perceived that the most part of the aircrew are sitting down in the cockpit, as happens with the pilots. However, several factors that happens in an aircraft, like vibrations, accelerations, and 3-axes movements, keep the muscles active to react and stabilize against forces [31], while muscle contractions are even harder when the air-crew stand up to perform their task [3]. Despite the mechanics having higher values for the fat-free mass of the trunk, they also had greater fat mass in this anatomical region when compared to medical personnel. Fat exceedances are normally stored in the abdominal region of the trunk, especially in men [26,32]. If we analyze these two factors together, the results suggest a better activation of the core muscles in the mechanics, but worse nutrition habits than the medical personnel. Healthcare professionals probably have a deeper knowledge of good nutrition habits that could help them to maintain healthier levels of fat, and that could balance their least muscle activation in flight [34]. In any case, it is important to notice that both the aerobic and anaerobic metabolism are activated in an aircraft, as was reported in real flight research [3], and it would be beneficial for these populations to maintain physical training that could help them to perform well in their job environments.

Body water results reinforced the previous assumptions about a greater muscle mass in mechanics than in the medical personnel. Muscle mass is mainly built of water, and there is a coherent relationship between the fat-free mass of the upper extremities and the trunk segments, and higher values of body water [30]. Both body water and fat-free mass, were higher in the right arm than in the left arm for each specialty, which suggests a predominance of the right hand (usually the dominant hand) in the tasks that both job groups must accomplish. If we compare their values with previous research, both mechanics and medical personnel had worse body composition values than pilots [4], and other transported units that usually required to perform high levels of physical activity. Even though there are similarities between transport aircrews, there are still subtle differences related to their occupation needs, and there is a need to monitor and provide body composition standards that gather these gaps [11,27]. Good nutrition habits [35] and training preparation [22] would be beneficial in these units to help them face the hazards that military aircrews need to cope with, both in flight time and when they are deployed.

Practical application

The practical application of this study emphasizes the necessity for air forces to implement specialized training and nutrition programs tailored to the unique demands of different aircrew specialties. Recognizing the specific body composition needs of medical personnel and mechanics can lead to more effective health and performance outcomes, contributing to enhanced operational readiness and safety in aerial missions. This approach supports the development of targeted interventions that promote optimal physical conditioning and well-being among aircrew members, ultimately improving their capacity to handle the physical challenges of flight duties.

Limitations of the study and future research lines

The study's limitations include its narrow focus on specific aircrew specialties within a single air force, potentially limiting the generalizability of the findings to broader populations or different military contexts. Additionally, the cross-sectional design precludes causal inferences between body composition and occupational roles. Lastly, we did not register the years of work experience in this sample, which may help to develop longitudinal studies to assess the evolution of body composition with and without dietary and training interventions. Future research should expand to longitudinal studies across diverse military settings to explore the dynamic changes in body composition over time and their impact on aircrew performance. Investigating the effectiveness of tailored training and nutrition interventions in enhancing operational efficiency and reducing injury risks in varied aircrew roles will also be valuable.

CONCLUSIONS

There are small differences in body composition between aircrew specialties (mechanics and medical personnel) primarily based on a greater body mass index, weight, body water, skeletal muscle mass, soft lean mass, and fat-free mass of the mechanics. Body composition analysis by segments, suggests better muscle activation during their duties, but worse nutrition habits in mechanics when compared to medical personnel. The performance requirements of these units are different from those that are principally responsible for the aircraft (pilots) or those who are transported to be deployed in a conflict area. Perceived assumptions about the tasks that each unit must accomplish need to be clarified by an adequate body composition assessment.

This information could help to understand better each unit requirements and to develop training and nutritional habits that are crucial to performing well in the stressful job contexts of the aircrews.

Conflicts of interest and sources of funding
The authors declare no conflict of interest. This research received no external funding.

Acknowledgments
We would like to acknowledge the contribution of the Aerospace Medicine Instruction Centre of Spanish Air Forces (Centro de Instrucción de Medic-ina Aeroespacial, CIMA), including the colonel, the military instructors, and the medical service personnel for their excellent work and collaborative spirit towards the present research.

Authors' contribution
Conceptualization, V.J.C.S. and A.B.S.; methodology, V.J.C.S. and A.B.S.; formal analysis, V.J.C.S. and A.B.S.; investigation, V.J.C.S. and A.B.S..; resources, V.J.C.S. and A.B.S.; data curation, A.B.S.; writing—original draft preparation, A.B.S.; writing—review and editing, V.J.C.S. and A.B.S..; supervision, V.J.C.S.; project administration, V.J.C.S.. All authors have read and agreed to the published version of the manuscript.

Ethics approval and consent to participate
The study was conducted in accordance with the Declaration of Helsinki and approved by the Institutional Review Board (or Ethics Committee) of UNIVERSIDAD EUROPEA DE MADRID (protocol code CIPI/18/093).

Patient consent for publication
Informed consent was obtained from all subjects involved in the study. Written informed consent has been obtained from the patient(s) to publish this paper.

Abstract: *Multiple endocrine neoplasias (MEN) represent a rare and intricate group of disorders with diverse endocrine and extra-endocrine manifestations. Among the five identified types of MEN syndromes, MEN 2 stands out due to its complexity, featuring medullary thyroid carcinoma (MTC), pheochromocytoma, and primary hyperparathyroidism (PHPT). MEN 2 is inherited in an autosomal dominant manner, with nearly a 100% lifetime risk of developing MTC, which can be fatal if not detected early. Comprehensive diagnostic protocols and timely interventions significantly mitigate morbidity. To guide surgical decisions, management strategies include regular imaging and biomarker monitoring (calcitonin, CEA, metanephrines/normetanephrines, and parathyroid hormone). Genetic screening of at-risk families and prophylactic thyroidectomy remain cornerstone preventive measures. Although tyrosine kinase inhibitors are generally reserved for specific cases of MTC and are not first-line therapies for MEN2-associated tumors, they hold the potential for mitigating tumor progression and recurrence despite the risk of endocrine dysfunction. This paper presents a narrative review focusing on multiple endocrine neoplasia type 2 (MEN2) syndrome, encompassing its genetic underpinnings, clinical presentations, diagnostic modalities, and therapeutic approaches. A total of 48 articles were included in this review.*

Keywords: *multiple endocrine neoplasia, medullary thyroid carcinoma, pheochromocytoma, primary hyperparathyroidism*

INTRODUCTION

Multiple endocrine neoplasias (MEN) are rare hereditary syndromes characterized by the co-occurrence of multiple endocrine tumors in the same individual or related individuals of the same family; these tumors usually secrete hormones that give rise to distinct clinical syndromes [1,2]. Currently, five distinct types of MEN have been identified: MEN1, MEN2 (previously known as MEN2A), MEN3 (formerly known as MEN2B) and the recently recognized MEN4 and MEN5 (Table 1) [3–11].

MEN 2 is a complex autosomal dominant inherited syndrome characterized by medullary thyroid carcinoma (MTC), pheochromocytoma, and primary hyperparathyroidism (PHPT)[12,13].

The estimated prevalence of MEN2 is approximately 1 in 35,000 [3]. More than 95% of MEN2 patients develop MTC, and about 50% have pheochromocytomas. HPT occurs in 20–30% of MEN2 patients, generally without evident symptoms, and is found by biochemical and imaging assessments [14].

The majority of pathogenic variants associated with Multiple Endocrine Neoplasia type 2 (MEN2) follow an autosomal dominant inheritance pattern and are situated within the extracellular cysteine-rich domain of the RET proto-oncogene's exon 10 (specifically at codons 609, 611, 618, or 620) or exon 11 (at codon 634). Pathogenic variants at codon 634 are responsible for at least 50% of diagnosed cases [13-20]. Approximately 25% of these cases are hereditary due to activating mutations in the REarranged during Transfection (RET) proto-oncogene. The course of MTC is indolent, and survival rates depend on the tumor stage at diagnosis. Initial management involves total thyroidectomy with bilateral dissection of the central node compartment [22]. Serum calcitonin and carcinoembryonic antigen should be performed pre-operatively. These can be followed over time and used as markers of disease recurrence as their doubling times have been shown to correlate with disease progression and survival [8]. Neck metastases appear early during MTC. Distant metastases are detected in 7-17% of all cases at the time of diagnosis and frequently appear in multiple sites. The most frequent sites of distant metastasis are the liver (49%), bones (45%), and lungs (35%) [23].

Table 1: Update in the classification of MEN syndromes [8–11]

	MEN1 (Wermer Syndrome)	**MEN2 (Sipple syndrome)**	**MEN 3 (Gorlin-Vickers syndrome)**	**MEN4 (MEN X syndrome)**	**MEN5**
Gene alteration	Loss-of-function of the tumor suppressor gene MEN1 (menin)	Germline variants in the *RE*arranged during *T*ransfection proto-oncogene (specially codon 634)	Germline variants in the *RE*arranged during *T*ransfection proto-oncogene (specially codon 918)	Inactivating germline mutation of tumor suppressor gene CDKN1B	Heterozygous missense variant in MAX (only 2 families described in the literature)
Inheritance	Autosomal-dominant	Autosomal-dominant	Autosomal-dominant	Autosomal-dominant	Autosomal-dominant
Dominant endocrine pathology	Primary hyperparathyroidism 85% - usually four-gland hyperplasia	Medullary thyroid carcinoma 95-100%	Medullary thyroid carcinoma 95-100%	Primary hyperparathyroidism 75%	Pheochromocytoma
Associated endocrine disorders	Enteropancreatic tumor: gastrinoma, insulinoma, non-functioning, glucagonoma, VIPoma Pituitary neuroendocrine tumors Bronchopulmonary neuroendocrine tumors, Thymic neuroendocrine tumors Adrenal cortical tumors (usually non-functioning)	Pheochromocytoma (50%) Primary hyperparathyroidism (20-30%): four-gland hyperplasia or single adenoma	Pheochromocytoma (50%)	pNET: non-functional, gastrinoma	Pituitary neuroendocrine tumors Parathyroid adenomas
Associated non-endocrine tumors or disorders	Breast cancer lipomas, angiofibromas, collagenomas, meningiomas	Cutaneous lichen amyloidosis (or) Hirschsprung's disease	Ganglioneuroma of the lips, tongue, or gastrointestinal tract + Marfanoid habitus (95%)		Ganglioneuromas, Neuroblastomas, Chondrosarcoma, Lung adenocarcinoma

The American Thyroid Association (ATA) stratified patients with MEN2 from moderate to the highest-risk groups based on the identified pathogenic variant in RET proto-oncogene and the severity of the clinical course of MTC [24]. According to the 2015 ATA guidelines, the highest-risk pathogenic variant includes MEN3 patients with RET mutations in codon p.Met918Thr [8,25]. High-risk MEN2 pathogenic variants are RET codon p.Cys634 and p.Ala883Phe pathogenic variants. Moderate-risk pathogenic variants include identified RET codon pathogenic variants other than those noted to be at "high" or "highest risk"[26,27].

In metastatic MTC, the focus is on local and systemic treatment modalities. Surgery remains the first recommendation for recurrent cases, dependent on factors like size, extent, and concurrent distant metastases. External beam radiation therapy (EBRT) may be considered when surgical resection is not feasible. Focal treatments such as surgery, embolization, radiofrequency ablation, and EBRT aim at relieving local symptoms and reducing the risk of complications. Embolization or chemoembolization for liver metastases may reduce tumor masses and alleviate symptoms. Multikinase and selective kinase inhibitors represent the systemic treatment for MTC with identified RET mutation [28]. Multikinase inhibitors with anti-RET activity, such as Vandetanib and Cabozantinib, are approved for MTC patients ineligible for surgery with symptomatic or progressive disease [29]. Despite benefits, these inhibitors have limitations, including toxicity impacting quality of life, unclear overall survival benefits, and the potential for tumor cell resistance [28].

Two new highly selective RET inhibitors — Selpercatinib and Pralsetinib — have shown promising results in MTC patients with a RET mutation, regardless of mutation or the number or type of prior systemic therapies received. Selpercatinib exhibited marked antitumor activity in RET-mutant MTC patients, even in those previously treated with Vandetanib or Cabozantinib [30]. Pralsetinib demonstrated increased RET potency and selectivity, with a positive response in RET-mutant MTC patients [31].

Pheochromocytomas are the first manifestation of MEN2 in 13-27% of cases [32]. The clinical picture is similar to that of the sporadic type (hypertension, headache, increased sweating, and tachycardia). However, MEN2-related pheochromocytomas are more likely to be bilateral when compared with sporadic ones. Primary hyperparathyroidism (PHPT) is typically mild and manifests concurrently or after MTC [1].

The objective of this paper is to provide a comprehensive review of multiple endocrine neoplasia type 2 syndrome, focusing on its genetic basis, clinical manifestations, diagnostic approach, and management strategies.

MATERIALS AND METHODS

Search Strategy

A comprehensive literature search was conducted to identify relevant studies on MEN2 syndrome, focusing on treatment strategies and outcomes. The search strategy encompassed electronic databases and academic repositories from January 1995 to February 2024. The following databases were utilized: PubMed/MEDLINE, Scopus, Web of Science, and Embase.

The search strategy combined Medical Subject Headings (MeSH) terms and free-text keywords, including but not limited to: "Multiple Endocrine Neoplasia Type 2", "MEN2 syndrome", "Medullary Thyroid Carcinoma", "Pheochromocytoma", "Hyperparathyroidism", "RET proto-oncogene", "Genetic testing", "Tyrosine kinase inhibitors", "Thyroidectomy", "Treatment outcomes", "Prophylactic surgery", "Patient outcomes", "Targeted therapy", "Clinical trials".

The search paradigm included combinations of Boolean operators (AND, OR) to refine the search results. Example search strings used were: "Multiple Endocrine Neoplasia Type 2" OR "MEN2 syndrome" AND "treatment" OR "selective RET inhibitor", "Medullary Thyroid Carcinoma" OR "MTC" AND "genetic testing" OR "prophylactic thyroidectomy".

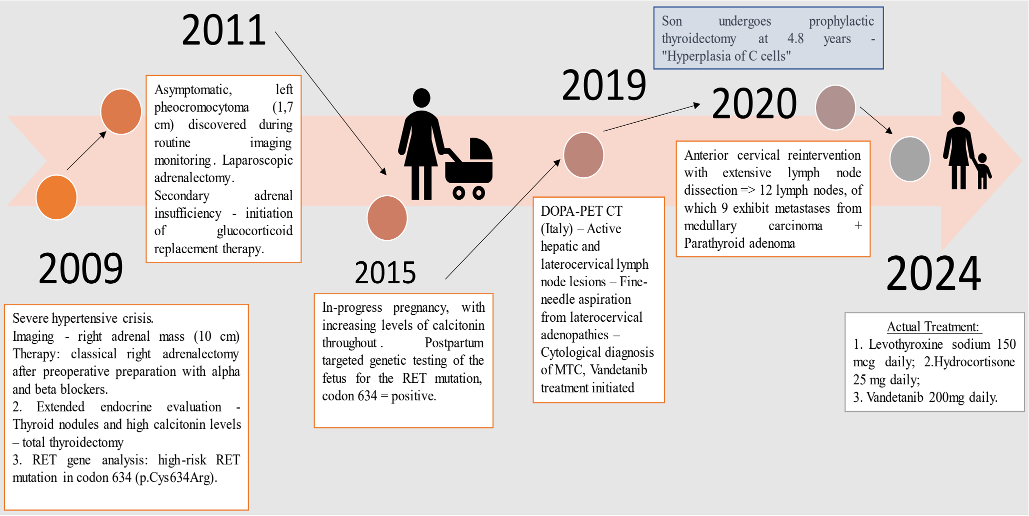
Inclusion criteria encompassed peer-reviewed articles, clinical trials, reviews, and observational studies published in English. Exclusion criteria included non-English articles, case reports, letters, and studies not directly related to MEN2 syndrome treatment or outcomes.

Two independent reviewers screened titles and abstracts for relevance. Full-text articles meeting inclusion criteria underwent detailed review. No third reviewer was involved. Data extraction included study design, participant characteristics, interventions, outcomes, and key findings.

A Journey from Personal Medical Cases to Broader Horizons

We presented the clinical case of a 37-year-old patient diagnosed with MEN2 syndrome, characterized by bilateral benign pheochromocytomas, medullary thyroid carcinoma with recurrent disease, and liver metastasis (Figure 1). In her 20s (in 2009), following a severe hypertensive episode and palpitations, abdominal ultrasonography raised suspicion of an adrenal gland tumor.

Figure 1: The evolution of a patient with MEN2 syndrome over 25 years



Asymptomatic, left pheocromocytoma (1,7 cm) discovered during routine imaging monitoring. Laparoscopic adrenalectomy. Secondary adrenal insufficiency - initiation of glucocorticoid replacement therapy.

Severe hypertensive crisis.
Imaging - right adrenal mass (10 cm) Therapy: classical right adrenalectomy after preoperative preparation with alpha and beta blockers.
2. Extended endocrine evaluation - Thyroid nodules and high calcitonin levels – total thyroidectomy
3. RET gene analysis: high-risk RET mutation in codon 634 (p.Cys634Arg).

In-progress pregnancy, with increasing levels of calcitonin throughout. Postpartum targeted genetic testing of the fetus for the RET mutation, codon 634 = positive.

DOPA-PET CT (Italy) – Active hepatic and laterocervical lymph node lesions – Fine-needle aspiration from laterocervical adenopathies – Cytological diagnosis of MTC, Vandetanib treatment initiated

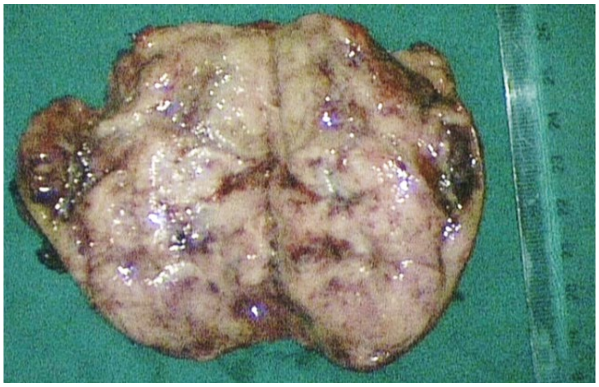
Son undergoes prophylactic thyroidectomy at 4.8 years - "Hyperplasia of C cells"

Anterior cervical reintervention with extensive lymph node dissection => 12 lymph nodes, of which 9 exhibit metastases from medullary carcinoma + Parathyroid adenoma

Actual Treatment:
1. Levothyroxine sodium 150 mcg daily; 2.Hydrocortisone 25 mg daily;
3. Vandetanib 200mg daily.

The diagnosis was confirmed by biochemical tests (increased plasma and urinary metanephrines and normetanephrines levels) and MRI, which visualized an ovoid tumor with a diameter of about 10 cm. Therapy with alpha and beta blockers was initiated for preoperative preparation, and later, a classical right adrenalectomy was performed. Examination of the surgically removed adrenal gland revealed multicentric, predominantly alveolar pheochromocytoma (Figure 2).

Figure 2: Macroscopic appearance of the resected adrenal gland including the pheochromocytoma tumor



After the discovery of pheochromocytoma, an extensive endocrine evaluation was conducted, revealing high levels of calcitonin (>2000 pg/ml) and multiple heterogeneous thyroid nodules. A neck ultrasound revealed bilateral thyroid nodules. One month following her right adrenalectomy, the patient underwent total thyroidectomy with bilateral dissection of central and lateral lymph nodes of the neck. The thyroid lobes were submitted separately and were enlarged. Well-circumscribed nodules were seen with nests of round cells among fibrous stroma. The histopathological result of the thyroid indicated the presence of thyroid medullary carcinoma.

Given the young age of disease onset and pathological confirmation of the diagnosis of 2 neuroendocrine tumors, suspicion of MEN2 syndrome was raised, and genetic testing to identify RET gene mutations was performed. When the high-risk RET mutation on codon 634 was found, and considering the patient's young age, the potential risks of the condition being passed on to children were discussed with her. While awaiting genetic screening results, biochemical, hormonal, and imaging tests were initiated for all family members. Calcitonin, parathyroid hormone, calcemia, normetanephrine and metanephrine values in plasma and urine were normal, and no thyroid nodules were detected by USG screening among her first-degree relatives. During the years 2009–2011, following the surgical interventions, the patient's condition improved. In 2011, with no characteristic signs, during biannual monitoring, a CT of the abdomen detected a tumor (1.7 cm) on the left adrenal. Laparoscopic left adrenalectomy was performed, and glucocorticoid substitution treatment was initiated.

Between 2012 and 2014, the patient stopped attending endocrinological consultations, and in 2015 she returned for follow-up when she declared she was pregnant and an increase in calcitonin levels was observed during pregnancy. After childbirth, although the calcitonin level did not normalize, it significantly decreased compared to the values at the end of pregnancy. Following birth, the child underwent targeted testing for a mutation in the RET proto-oncogene at codon 634, yielding a positive result (Figure 3). Prophylactic thyroidectomy was performed at the age of 4.8 years. The histopathological result revealed the presence of C-cell hyperplasia.

Figure 3: Targeted testing for RET proto-oncogene indicated the mutation on the level of codon 634-p.Cys634Arg

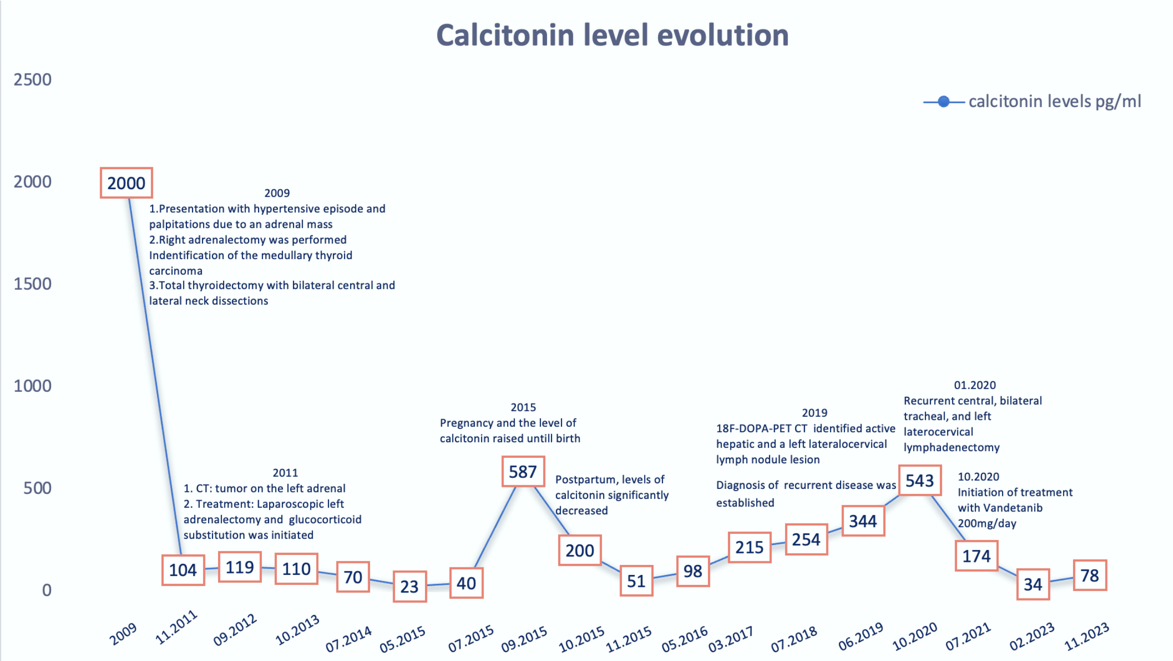
Annual reassessments of our patient revealed persistently elevated calcitonin levels. In 2019, due to increasing calcitonin levels, an 18F-DOPA-PET CT scan was conducted in Italy. The results described in the cervical and hepatic regions were suspicious of neoplastic pathology (recurrence) with high absorption of the dopamine tracer. Upon returning to Romania, after performing a fine-needle aspiration from the pointed nodule, the diagnosis of recurrent disease was established.

Recurrent central, bilateral tracheal, and left laterocervical lymphadenectomy was performed in January 2020. Although only one parathyroid gland was removed, the findings suggested parathyroid adenoma. The histopathological diagnosis confirmed the presence of twelve lymph nodes, nine of which exhibited metastases of medullary carcinoma with amyloid stroma.

Following surgical intervention, due to consistently increasing levels of calcitonin and concurrent secondary hepatic determinations, Vandetanib treatment was initiated in October 2020. In subsequent biannual follow-ups, calcitonin levels did not normalize, but there was a significant decrease compared to the values before the initiation of tyrosine kinase inhibitor therapy. Figure 4 presents the evolution of calcitonin levels from 2009 to 2023.

Figure 4: The evolution of the calcitonin level and the main events in the evolution of the patient



Levels of plasma and urinary metanephrines/ normetanephrines, serum calcium, and parathyroid hormone (PTH) remained stable and within normal ranges throughout the monitoring period after the second adrenal surgical intervention.

The serum PTH level was also normal, including the assessment preceding the surgical re-intervention for the local recurrence of medullary thyroid carcinoma (CMT), during which a parathyroid adenoma was also detected.

Recent laboratory tests have shown stable values, indicating a favorable therapeutic response to the tyrosine kinase inhibitor.

At present, the patient is receiving thyroid and glucocorticoid substitution: 25 mg of cortisone daily and L-thyroxine 150 mcg daily. Additionally, she has been undergoing Vandetanib 200 mg daily treatment since October 2020, for approximately 3.5 years. Calcitonin and CEA values remained stable under this therapy. However, consideration is being given to switching to Selpercatinib, a highly selective RET inhibitor, in the future.

Results of the Narrative Review

In our review, we examined 34 papers to assess their relevance to MEN2 syndrome, and 26 of these papers met our inclusion criteria. Here, we present a summary of the findings from these studies.

The MEN2 syndrome encompasses several neuroendocrine tumors, including medullary thyroid carcinoma (MTC), pheochromocytoma (PCC), and primary hyperparathyroidism (PHPT) [33]. MTC, being the most prevalent and potentially life-threatening component, typically manifests first within the syndrome [31].

The development and severity of tumors in MEN2 syndrome are significantly influenced by specific mutations in the RET gene [34,35]. Prophylactic thyroidectomy is strongly recommended for individuals harboring these mutations, ideally before the onset of MTC [34,35].

Clinical presentations vary, with MTC often presenting as thyroid nodules or symptoms associated with elevated calcitonin levels, while PCC may manifest with symptoms such as palpitations, headache, and diaphoresis. Hyperparathyroidism in MEN2 is frequently asymptomatic and is commonly diagnosed alongside MTC [8].

Surgical removal of MTC and any associated metastases is essential for achieving a favorable outcome [36]. Prognosis in MEN2-related MTC largely hinges on the disease stage at diagnosis [14,37].

Compared to sporadic cases, hereditary MTC typically appears at a younger age and displays distinct pathological features [38–41].

Post-surgery, patients with persistently elevated calcitonin levels require vigilant monitoring using biochemical markers to detect recurrence and assess disease progression effectively [27,42,43].

This narrative review underscores the complex nature of MEN2 syndrome, highlighting its genetic basis, clinical manifestations, therapeutic strategies, and the critical role of ongoing surveillance in managing patient outcomes effectively.

DISCUSSION

MEN2 syndrome consists of several neuroendocrine origin abnormalities: MTC, PCC, and PHPT. Diagnosis of any of these tumors implies correlative analyses and undertaking further investigations for the detection of the other possible associated neoplasia [33]. The case emphasizes the importance of the radical approach to MEN 2 syndrome from both a therapeutic and surgical point of view. The key to the MEN2 phenotype is that the frequency and severity of specific tumors depend on the specific causative mutation (genotype). MEN2 patients with RET mutations require a prophylactic thyroidectomy, that is, ideally, before MTC has developed [34,35]. The timing of this is based on the risk stratification of the RET mutation described by the American Thyroid Association [26].

MTC may present with a thyroid lump or symptoms of calcitonin excess, like diarrhea and flushing. Pheochromocytomas may present with the classic triad of palpitations, headache, and diaphoresis, but can be asymptomatic upon diagnosis. They often exhibit bilateral involvement, and unilateral presentations frequently lead to the development of a contralateral pheochromocytoma within 10 years. Pheochromocytomas in MEN2 syndrome are seldom malignant and the prognosis in MEN2 is primarily influenced by MTC, the most life-threatening component. Hyperparathyroidism in MEN2 is generally without symptoms and is diagnosed concurrently with MTC [8].

One dermatological manifestation associated with MEN2 syndrome is cutaneous lichen amyloidosis (CLA), frequently co-existing with pheochromocytomas. Additionally, reported cutaneous conditions linked to MEN2 comprise dermal hyperplasia and multiple sclerosing fibromas [14].

MTC develops in almost all MEN 2 cases and is usually the first manifestation of the syndrome. Before MTC develops, it is preceded by thyroid C-cell hyperplasia. MEN 2 MTC is typically multifocal and often bilateral [31]. Only a few MEN 2 patients are symptomatic at MTC diagnosis. A recent nationwide population-based study reported that only 15% of the MEN 2 cases with MTC had clinically suggestive characteristics at diagnosis, while the remaining 85% were diagnosed by screening [44]. MTC can result in fatal outcomes within the spectrum of MEN2 when managed ineffectively or remains unrecognized. Because MTC frequently involves the cervical lymph nodes, lymph node dissection, in addition to total thyroidectomy is required [36]. Complete surgical resection of the thyroid tumor and any locoregional metastases is the only curative option for locoregional MTC. Therefore, early diagnosis and detection of MTC are very important for prognosis [38].

There are several key differences in the presentation of hereditary compared to sporadic MTC [39]. Hereditary MTC presents at a significantly younger age, even after excluding patients identified via genetic screening. It is usually diagnosed in the 2nd - 3rd decade [45]. Depending on the specific RET variant, the mean age at diagnosis of normal thyroid/C cell hyperplasia ranges from 5 to 11 years, while the mean age at diagnosis of node-negative MTC ranges from 19 to 33 years [46][40]. In a large cohort of patients with MTC, Saltiki et al. found that compared to sporadic MTC, hereditary MTC patients had significantly more microscopic disease, multifocality, C-cell hyperplasia, and smaller tumor size [41]. Sporadic MTC patients had significantly more capsular invasion, soft tissue invasion, and distant metastases than hereditary MTC patients [42]. According to research, there is a tendency towards a more unfavorable progression in the case of sporadic MTC, and the presented case supports this notion, highlighting the hepatic metastases 10 years after the initial diagnosis of MTC.

In patients with persistently high levels of calcitonin after surgery, biochemical markers with calculated doubling times have been used to monitor MTC recurrence, progression, and survival. Barbet et al. (2005) found in multivariate analysis that calcitonin and carcinoembryonic antigen (CEA) doubling times are independent risk factors for survival. When calcitonin doubling time was 2 years, 100% of patients were alive at 10 years [43]. Some limitations of calcitonin include inter-assay variability, a concentration-dependent half-life, and rapid degradation at room temperature or refrigeration. With the development of increasingly reliable assays, investigation into other biomarkers continues [42].

Survival for patients with MEN2-related MTC treated surgically is dependent upon the disease stage at diagnosis [47]. Post-resection, all patients with MEN2 should be followed with surveillance for recurrent disease. In addition, any patients with MTC, or a constellation of two MEN2 tumors, should undergo RET genetic testing. Children of MEN2 patients should have genetic testing performed within the first 6 months of life [48,49]. Calcitonin and CEA are markers used to assess initial disease burden and followed post-resection to assess disease progression in patients with metastatic MTC [27].

Distance metastasis of MTC depends on tumor stage and calcitonin level. Liver metastases are observed in 13% of MTC with a serum Calcitonin level of more than 400 pg/ml. Liver metastases are generally hypervascular and exhibit variable atypical imaging appearances, therefore, the differentiation between them and other vascular hepatic lesions, especially hemangioma, is challenging. State-of-the-art 68GaDOTA-somatostatin analogue-PET/CT improves specificity in detecting the metastases of NET, especially in liver and lymph nodes; nevertheless, this imaging technique is not yet a routine protocol [50,51].

Before thyroidectomy, the presence of pheochromocytoma should be ruled out by appropriate biochemical analysis in all MEN 2 and MEN 3 patients [52]. If a pheochromocytoma is detected, adrenalectomy should be performed before thyroidectomy or other surgery to avoid severe intraoperative complications. Laparoscopic adrenalectomy is the gold standard in the treatment of pheochromocytoma. Limitations only arise because of technical difficulties or tumor size. Pheochromocytoma is an infrequent initial presentation of MEN2 and is typically recognized during screening evaluations in MEN2 patients [53]. It typically becomes apparent approximately a decade following the onset of MTC or C cell hyperplasia [37]. In our case, the patient presented initially with unilateral, benign left pheochromocytoma, whose symptoms manifested before the diagnosis of medullary thyroid carcinoma. Due to the large dimensions of the adrenal adenoma (10 cm), surgery was performed through the classical approach. When contralateral adrenal involvement was detected 2 years later, the tumor dimensions (1.7 cm) allowed for a laparoscopic approach.

According to the literature, pheochromocytoma has a variable penetrance in MEN2A patients, depending on the mutation of RET [54]. The highest frequency is found in patients with a mutation of codon 634 [55]. It is frequently bilateral, multicentric, and not always synchronous. Patients require alpha blockade, with or without beta-blockade, before and during surgery.

Finally, in MEN2 patients with parathyroid adenomas, open neck exploration is recommended with the removal of enlarged parathyroid glands only, rather than the more aggressive approach adopted for parathyroid tumors in MEN1 patients [56]. Recurrence is uncommon [8]. The clinical manifestations of MEN2-related PHPT are similar to sporadic cases, including nephrolithiasis, osteopenia or osteoporosis. Although parathyroid hyperplasia is more common in MEN syndromes, in the presented case, the discovery of a single parathyroid adenoma was made incidentally, intraoperatively, in the context of the surgical intervention for the removal of metastatic lateral cervical lymph nodes.

What draws our attention and raises questions in this case, are the markedly elevated levels of calcitonin in the last trimester of pregnancy, with a sudden decrease in the last 2 weeks of pregnancy and postpartum. Studies in the literature regarding changes in calcitonin levels throughout pregnancy among patients with a personal history of MEN2 syndrome are limited.

Considering the rare cases described in the literature of an association between MEN2 and pregnancy, we can take this as a limitation of the current study. We can also add the lack of specific guidelines to help manage such a case where elevated calcitonin values are recorded during pregnancy.

As directions for future research, we will consider the continued development of generations of MTTs, which have minimal toxicity and greater specificity for mutated RET and whose purpose is to either cure patients with advanced MTC or change their progressive illness into a chronic, long-lasting.

That is why, in the future, we will be committed to forming and monitoring further studies with larger sample sizes and long-term follow-up to draw definitive conclusions.

CONCLUSIONS

MEN2 is a rare hereditary disorder distinguished by MTC, either unilateral or bilateral pheochromocytoma and primary parathyroid hyperplasia. The risk of developing MTC over one's lifetime is almost 100%, with varying expressions of other symptoms. Neglected or undetected, MTC within the context of MEN2 can lead to fatal outcomes.

Yet, timely identification and thorough diagnostic protocols enable prompt interventions, thereby reducing the associated morbidity and mortality linked to MEN2.

Imaging check-ups in combination with annual monitoring of calcitonin, CEA, metanephrines/normetanephrines, and parathyroid hormone in a patient with MEN 2 syndrome are practical ways to supervise the case, make timely decisions about surgical intervention, and prevent complications.

Genetic testing of MEN2 families and prophylactic thyroidectomy are mandatory. In cases where there is a family history of the RET mutation gene, a proactive approach to performing thyroidectomy significantly reduces the risk of complications and death, as evidenced by the positive outcome observed in our patient's son.

Even in the face of repeated endocrine challenges and recurring illnesses, the potential for utilizing tyrosine kinase inhibitor therapy stands as a robust choice in managing tumors associated with MEN2 syndrome.

By intertwining our clinical observations with established literature, we navigate the complexities of MEN 2 syndrome management. This blend of personalized care and evidence-based medicine sheds light on the nuanced treatment of MEN 2 syndrome. Over 25 years of patient follow-up, we witness sustained health and improved quality of life. As we evolve alongside advancements in targeted systemic therapies, our approach remains grounded in comprehensive understanding and patient-centered care.

Abstract: *The primary objective of this narrative review is to evaluate the most frequently recommended structural and functional imaging methods in managing epilepsy cases as effectively as possible from a neurologist's perspective. This review examines the background of current practice, from the beginnings of neuroimaging by computer tomography to the newly introduced methods and their combination, which helps diagnose and monitor these patients. The neuroimaging investigations required for the presurgical evaluation of patients with epilepsy are presented, and recommendations for specific MRI protocols are provided. The clinical use of functional imaging methods is also considered, and correlations between clinical aspects and specific imaging methods are explored, based on the retrieved data in the literature. In conclusion, this review emphasizes using functional and structural imaging methods, guided by clinical evidence, for better therapeutic management in patients with epilepsy.*

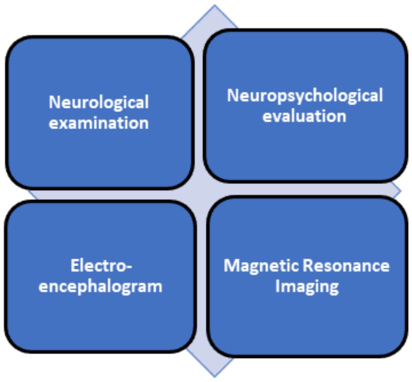
Keywords: *Positron Emission Tomography, Single-photon-emission computed tomography, medically refractory epilepsy, HARNESS protocol, MRI*

INTRODUCTION

Epilepsy is one of the most common neurological pathologies globally, with an incidence of 1-2% of the population [1]. According to the 2017 International League Against Epilepsy (ILAE) classification, seizures are stratified into focal, generalized, or unknown onset [2].

Differentiating focal onset from generalized onset seizures is sometimes very difficult because patients may present with bilateral tonic-clonic seizures without a clear description of the initial symptomatology and with inconclusive electro-encephalography (EEG) data. Neuroimaging is crucial because many etiologies can be diagnosed with its help. An epileptogenic area discovered by Magnetic Resonance Imaging (MRI) can support the focal onset of seizures and help for better therapeutic management, either surgical or pharmacological (Figure 1). Unfortunately, about one-third of epilepsy patients become drug-resistant [3]. In this situation, it is necessary to delimitate the epileptogenic area and surgically remove it [4]. The epileptogenic zone is defined by Lüders et al. as "the minimum amount of cortex that must be resected (inactivated or completely disconnected) to produce seizure freedom" [5].

Figure 1: Some non-invasive methods



A presurgical evaluation is necessary to decide which candidates are suitable. All patients with pharmacoresistant epilepsy should be evaluated for epilepsy surgery. This may cause or increase the risk of sudden unexpected death in epilepsy (SUDEP), which is why patients should be encouraged to have better therapeutic compliance [6]. This is also helped by good communication between doctor and patient; the better informed the patient is, the more chances there are to provide appropriate therapeutic management [7].

Regrettably, quite a significant number of patients are not considered or cannot access such a program. This happens mainly in underdeveloped or developing countries due to the need for more specialized medical personnel in this field [8].

In many situations, more than these are needed, and more advanced investigations are required (Figure 2) [9].

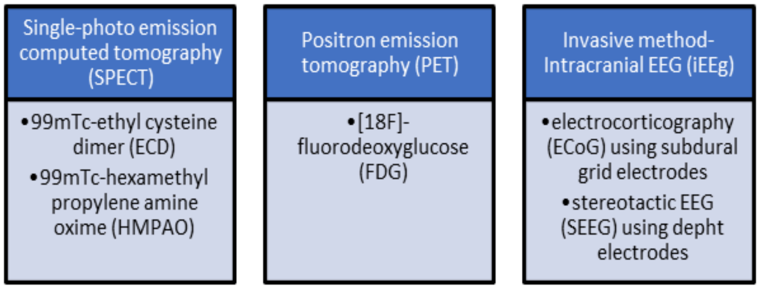


Figure 2: Advanced investigations

Single-photo emission computed tomography (SPECT)
•99mTc-ethyl cysteine dimer (ECD)
•99mTc-hexamethyl propylene amine oxime (HMPAO)
Positron emission tomography (PET)
•[18F]-fluorodeoxyglucose (FDG)
Invasive method-Intracranial EEG (iEEg)
•electrocorticography (ECoG) using subdural grid electrodes
•stereotactic EEG (SEEG) using depht electrodes

These investigations aim to determine the patient's chances of remaining seizure-free postoperatively and, of course, to minimize the post-surgery risks and functional dysfunction. After these steps have been taken, the next one would be to establish a few essential things: the symptomatic area, the irritative area, the ictal area, the epileptogenic area, and the eloquent area [10].

OBJECTIVE

This article aims to summarize the role of structural and functional imaging of the brain by use of CT, MRI, SPECT, FDG PET, and non-FDG PET radio-tracers in epilepsy from a multidisciplinary perspective. Our search strategy on PubMed included terms related to epilepsy, neuroimaging in epilepsy including PET and SPECT, and HARNESS protocol MRI, in studies published from 1995 until January 2024. Only papers published in English were selected.

RESULTS

A number of 44 primary and secondary reports have been selected to be included in the review. These sources explored both structural brain imaging techniques and functional neuroimaging investigations focused on diagnosing and monitoring epilepsy.

STRUCTURAL BRAIN IMAGING

Magnetic Resonance Imaging (MRI)

According to ILAE publications, a brain MRI should be performed after the first seizure to determine therapeutic attitude (Figure 3). It has a high specificity for detecting possible cortical malformations, including cortical dysplasia, mesiotemporal sclerosis, and other structural changes that have an increased epileptogenic effect and may also increase the risk of treatment resistance. As for epileptic syndromes, there is little evidence to recommend advanced imaging, but if abnormal neurological development, cognitive decline, treatment resistance, or focal interictal spikes occur, it should be considered and performed [11].

The ILAE Neuroimaging Task Force has proposed a set of acquisition sequences known as the optimal protocol for epilepsy, the "HARNESS"-MRI protocol (Bernasconi et al., 2019 – Figure 4) [11]. The optional sequences are Gadolinium-enhanced MR and Susceptibility-weighted imaging (SWI) [12].

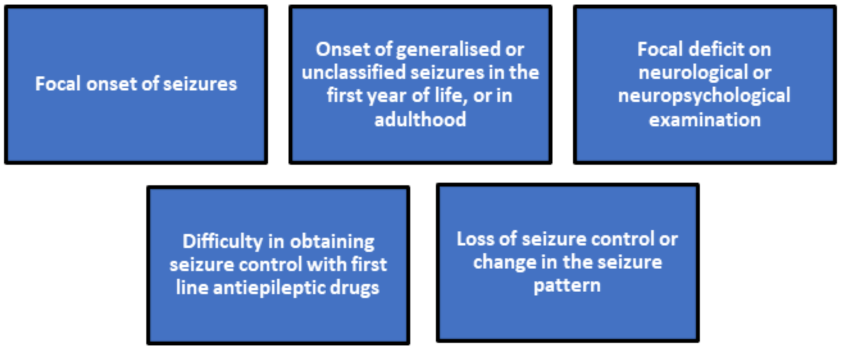
The role of structural MRI in detecting subtle structural abnormalities

Focal cortical dysplasia (FCD) is one of the most frequent structural changes requiring advanced imaging evaluation and the third most common etiology of medically intractable seizures in adults [13]. There are three types; the first type is associated with a late onset, in adulthood, with changes in the temporal lobe. Clinical symptoms are more severe in type 2, especially in children with predominantly frontal lobe changes. FCD type 2 correlates with other tumors like hippocampal sclerosis, tumor, vascular malformation, or attained pathology during early life [13]. FCD type 3 refers to malformation connected with different cortical lamination abnormalities with a main lesion within the same area/lobe. In a significant number of cases, especially FCD type 1, it may remain undetected.

Additional curvilinear reformatting and morphometric analysis of T1 and T2-FLAIR sequences may be helpful in this situation. For detecting these abnormalities, a satisfactory specificity of 90%, accompanied by a sensitivity of 50%, was observed only by FLAIR sequencing [14-17]. To avoid these limitations, an excellent therapeutic approach is to combine MRI with functional imaging, PET, or SPECT [18].

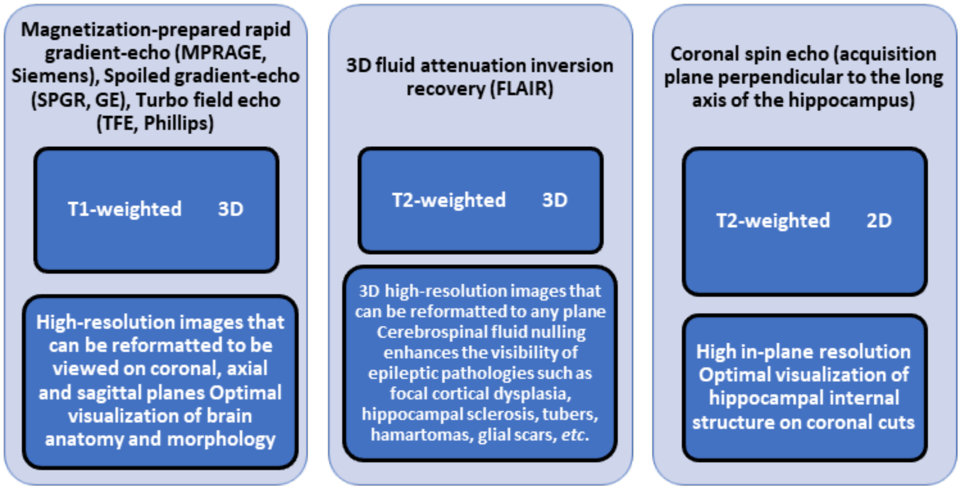
Another standard structural change (Figure 5) is temporal lobe epilepsy, particularly mesiotemporal sclerosis (MTLE). It refers to damage to the mesial or inner portion of the temporal lobe, with a focus on the hippocampus. This can result from various reasons, including infection, head trauma, or other causes [19]. Symptomatology is polymorphic but may include altered consciousness, memory disturbances, and emotional changes [20]. Patients usually have an increased risk of developing drug resistance, so it is important to refer them to a specialized center. Brain MRI is a central and essential method of diagnosis and assessment. It can show a certain level of atrophy in this area, increased T2 signal, and loss of hippocampal architecture [21,22].

Figure 3: Indications for magnetic resonance imaging (MRI) in patients with epilepsy [22]



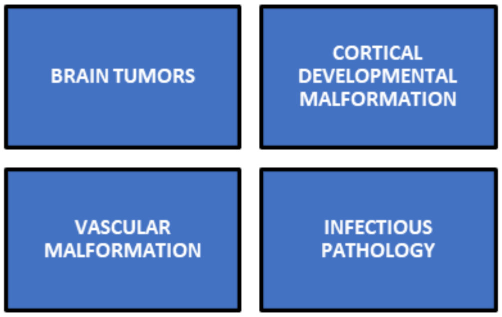
Focal onset of seizures
Onset of generalised or unclassified seizures in the first year of life, or in adulthood
Focal deficit on neurological or neuropsychological examination
Difficulty in obtaining seizure control with first line antiepileptic drugs
Loss of seizure control or change in the seizure pattern

Figure 4: Required sequences of the HARNESS-MRI protocol [11]



Magnetization-prepared rapid gradient-echo (MPRAGE, Siemens), Spoiled gradient-echo (SPGR, GE), Turbo field echo (TFE, Phillips)
T1-weighted 3D
High-resolution images that can be reformatted to be viewed on coronal, axial and sagittal planes Optimal visualization of brain anatomy and morphology
3D fluid attenuation inversion recovery (FLAIR)
T2-weighted 3D
3D high-resolution images that can be reformatted to any plane Cerebrospinal fluid nulling enhances the visibility of epileptic pathologies such as focal cortical dysplasia, hippocampal sclerosis, tubers, hamartomas, glial scars, etc.
Coronal spin echo (acquisition plane perpendicular to the long axis of the hippocampus)
T2-weighted 2D
High in-plane resolution Optimal visualization of hippocampal internal structure on coronal cuts

Figure 5: Other common epileptic pathologies



BRAIN TUMORS
CORTICAL DEVELOPMENTAL MALFORMATION
VASCULAR MALFORMATION
INFECTIOUS PATHOLOGY

Computed tomography (CT)

CT can play an essential role in the assessment of patients with epilepsy in certain situations. However, in general, CT is not used as the first option for diagnosing epilepsy but rather to rule out other causes of seizures or to identify possible brain damage. According to the American Academy of Neurology (A.A.N.), this investigation should be performed and recommended to all patients presenting with a first epileptic seizure, especially if they have an abnormal neurological examination or focal onset of the seizure [23]. The role of CT in epilepsy may refer to:

- Exclusion of other causes: CT may be performed to exclude brain lesions or abnormalities that could cause seizures. This may include tumors, vascular malformations, or traumatic injuries.

- Post-traumatic assessment: if the patient has suffered a severe head injury, CT may be used to assess any brain injury or bleeding that could be involved in triggering seizures.

- Preoperative guidance: in cases where epilepsy is resistant to treatment and surgery is considered an option, CT can guide the surgeon in pinpointing the exact brain area responsible for the seizures.

However, for a more detailed evaluation of the brain in epilepsy cases, other imaging techniques, such as MRIs, are usually preferred [24].

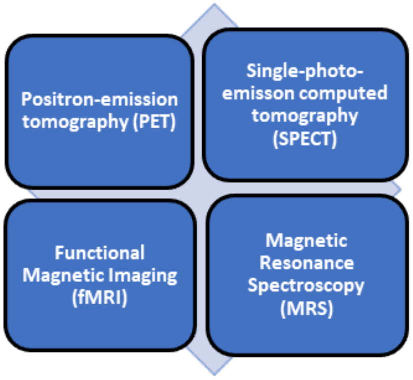
FUNCTIONAL IMAGING

Functional imaging (Figure 6) can help us when there are situations where structural imaging is not sufficient or there are negative results (negative MRI) to identify and demarcate the epileptogenic focus, or when multiple epileptogenic foci are detected [25].

A large proportion of patients with drug-resistant epilepsy, almost 50%, have no evident lesion found on brain MRI. In this situation, we can speak of a negative MRI. However, there are cases in which a second interpretation of the same investigation, accompanied by additional information, revealed the lesion [26]. In this case, it should be checked if the HARNESS protocol was used or if there are artifacts that require the imaging to be repeated.

Functional imaging is remarkable in that epileptogenic brain tissue has a different metabolism and electrophysiology than normal tissue. These regions of difference are then visually expressed and projected into existing structural images, usually MRI [27].

Figure 6: The most widely used functional imaging in epilepsy



Positron-emission tomography (PET)
Single-photo-emisson computed tomography (SPECT)
Functional Magnetic Imaging (fMRI)
Magnetic Resonance Spectroscopy (MRS)

Functional MRIs can be helpful when the patient is asked to do consecutive, usually simple, tasks. During this time, there may be changes in T2 sequences. This is why this investigation is recommended in some presurgical evaluations to detect hemispheric language dominance, especially when a resection of the dominant temporal lobe is planned [12]. Other indications include motor, somatosensory, or visual cortex mapping. It is beneficial in situations where there is the proximity of tumors or FCD to eloquent areas [28].

In general, areas with changes in contrast-dependent blood oxygenation levels are secondary changes in the ratio of deoxy- to oxyhemoglobin that occur during the performance of cognitive, motor, or other tasks, which permits us to map the neural pathways implicated in the delivery of these tasks. One of the most critical applications of this investigation is the localization and lateralization of cognitive function. A crucial step before surgery is to reduce the risk of causing a significant impairment. This is why a cooperative patient who can smoothly execute the indications and tasks is needed. This investigation is not recommended for patients who are claustrophobic, who have metal devices, or who are not able to perform tasks. For preoperative fMRI, it is advisable to choose appropriate procedures depending on the area of the brain to be resected [29].

In recent years, there has been a growing association between simultaneous electroencephalography monitoring and fMRI [30]. This method makes use of EEG changes, in particular, interictal spikes and discharges that may be associated with hemodynamic changes. This can have a significant impact on the therapeutic decision and case management [31].

Positron Emission Tomography

PET examination of the brain is used to observe a variety of images and biological phenomena such as blood flow, metabolism, protein and DNA synthesis, and more. This happens after injecting a radiolabelled compound.

Radiotracers are imprinted with a positron-emitting isotope manufactured by a cyclotron. After administration, they spread to different areas of the body, even to the brain, crossing the blood-brain barrier and gathering in the tissues to reveal the biological impact of the radiotracer. The mechanism of positron detection is via the coincidence system, which allows PET to have spatial resolution in the mm range. This also differentiates it from SPECT, which has a weaker resolution. Even though there are several PET Radiotracers, the most commonly used for epilepsy is FDG (18F-fluorodeoxyglucose) [32].

FDG-PET imaging

As mentioned above, when MRI and video EEG monitoring are not relevant, we can use PET, and the most common tracer in epilepsy is FDG-PET. This measures glucose metabolism linked to the synaptic and neuronal activity of the cerebral tissue. Even if there is not enough evidence for a precise time window, the indicated postictal period differs depending on the type of seizure. For focal aware seizures, interictal FDG-PET should be performed at least after 24h and 48h after focal impaired awareness and focal to bilateral tonic-clonic seizures. This is important because it can complicate the outcome of investigations. This can be misinterpreted, leading to erroneous lateralization because it should be interictal, and the basis of the interpretation is finding the ratio of hypometabolism to the contralateral side [33]. Another factor that can have an impact by lowering the rate of glucose metabolism is the use of some drugs, for example, barbiturates, valproic acid, phenytoin, and carbamazepine [34].

Some patients need sedation, which can be done 10 minutes before the examination. Several studies have shown that propofol sedation can reduce the rate of glucose metabolism and the rate of cerebral blood flow, which need to be taken into account when these procedures are required [35].

Usually, in interictal periods, FDG-PET shows hypometabolism in epileptogenic areas. This is directly related to seizure duration, frequency, and severity. An increased frequency also leads to increased hypometabolism area and vice versa [36]. There are also some particularities, such as in some cases of focal epilepsy, frontal or temporal, hypometabolism may be present in the ipsilateral thalamus, or contralateral cerebellar hypometabolism may be found especially in frontal lobe epilepsy [36].

In order to avoid false results that could mislead us by hypo or hypermetabolism, a proper strategy is to register the EEG during the 30-40-minute period of FDG capture. If this is not feasible, an epileptologist can be called in to follow the patient. EEG monitoring can be stopped once the patient enters the scanner.

In the case of temporal lobe epilepsies, the specificity and sensitivity are over 80%, but a unique contribution is made in situations where there are dual-pathology cases (coexistence of medial temporal and neocortical seizure foci) [37]. The localization of epileptogenic areas is diminished when dealing with frontal lobe epilepsy especially in some cases of occipital epilepsy [38].

Another essential feature is that FDG-PET can help assess the functionality of the remaining unresected brain tissue when an epileptogenic lesion has been taken into account for surgical resection. The post-surgical neurocognitive status is essential and also depends on the integrity and functionality of the remaining brain tissue.

Also, this type of patient can be associated with other comorbidities, and among the most common are cognitive disorders and depression that contribute to a decrease in quality of life. It has been shown that those with depression and epilepsy have a predisposition to ipsilateral or bifrontal hypometabolism [39]. PET studies in patients with temporal lobe epilepsy using a serotonin transporter ligand as a receptor have shown a decrease in its activity. This supports the hypothesis of using medication with selective serotonin reuptake blockers in patients with epilepsy and depression [40,41]. Memory deficits are among the frequent complaints of these patients. In those with occipital lobe seizures, deficits in verbal memory and executive function have been correlated with left temporal lobe hypometabolism. Patients with postictal amnesia were associated with disturbances in the left mid-temporal metabolism [42]. Under specific circumstances, other radio transmitters can be used, including [^{11}C] flumazenil, which has been shown to have a higher sensitivity to temporal lobe epilepsy, particularly hippocampal sclerosis [43].

SPECT

This type of imaging is used to measure cerebral blood flow in vivo. Although brain perfusion and metabolism are not the same type of process, they are connected in most situations [44,45]. The difference between FDG-PET and SPECT is the lower spatial but higher temporal resolution, leading to the detection of the seizure onset zone. Cerebral blood flow is strongly correlated with neuronal activity, so during the ictal phase, they increase concomitantly. Therefore, for an accurate interpretation of the results, it is necessary to precisely measure the dissimilarity between ictal and interictal SPECT results (which are interrelated with CT or MRI) [46]. The areas of hyperperfusion in the ictal phase are considered to have the most significant potential for delimiting the epileptogenic zone.

In general, interictal SPECT has a lower sensitivity compared to ictal SPECT. In the interictal period, hypoperfusion or normal perfusion may be observed in epileptogenic areas. Even when hypoperfusion is present, it can be of a relatively low intensity, making it quite hard to distinguish from normal tissue. Its primary role is to support the ictal assessment using SISCOM (subtraction ictal SPECT connected to MR imaging; that is, the interictal SPECT images are retrieved from the ictal photos, and the results are displayed on cosigned MR images), by furnishing a baseline blood flow [47].

However, logistics is not an advantage. The patient must be under constant medical supervision, with EEG monitoring and possibly tapering of antiepileptic medication to increase the possibility of a new seizure recurrence. The radiotracer should be placed at the patient's bedside for faster administration. So that immediately at the onset of a seizure, either announced by the patient or by clinical or EEG changes, the radiotracer can be injected. This is important because focal seizures, as we know, bilateralize quite quickly, and a late injection may miss the initial focus. Nevertheless, SPECT remains a crucial investigation in MRI-negative patients [48].

Magnetic resonance spectroscopy (MRS)

This investigation can measure different metabolites. Among those that are detectable are N-acetyl aspartate (NAA), choline, creatine, lactate, glutamate, and gamma-aminobutyric acid (GABA) [49].

Numerous studies examining various brain pathologies have found that NAA, which is predominantly found in neuronal mitochondria, is the most significant informative measure of neuronal function. On the other hand, creatine is found as well in neurons as in astrocytes, but the highest concentration is in the astrocytes [50]. Therefore, when considering the integrity of neuronal function, the NAA/creatine ratio is used. In epileptic patients with cortical anomalies, it has been shown that NAA values are specific to the epileptogenic area and have average values in patients with therapeutically controlled seizures. Even in those patients who have recurrent seizures but with non-epileptogenic structural abnormalities, there's a high likelihood of changing NAA levels [50].

Unlike other investigations, proton MRS does not typically include the whole brain in measurements, and sometimes, a few significant voxels are sampled with proton MRS. A relatively low signal-to-noise ratio is calculated, and this, together with the extended time taken to obtain the spectra, makes the technique of somewhat limited clinical use.

MRS may play a significant role in temporal lobe epilepsy because it is better defined clinically and anatomically. However, the same cannot be said for neocortical or extratemporal epilepsies. In this case, we have a much larger brain volume with the potential to trigger seizures with different propagation paths [51]. Other trials targeting MTLE groups have shown that bilateral metabolic alterations in these patients have predictive value for postoperative outcomes. So, those with significant bilateral or contralateral lesion metabolic changes had a much worse postoperative outcome through poor seizure control [52,53].

Results were compared with EEG localization and surgical results, showing that reduced NAA signal intensity can lateralize the epileptogenic area and those with focal epilepsy, especially MTLE. Nevertheless, these changes are often bilateral in patients with MTLE. After successful surgery, the NAA concentration can normalize [54].

CONCLUSIONS

Neuroimaging plays a vital role in the assessment and management of patients with epileptic seizures. Magnetic resonance imaging can lead to the detection of the etiology of focal seizures and the demonstration of anatomical changes associated with epileptic seizures. Even if its increased efficiency has been demonstrated in some situations, such as in the case of negative MRI or pharmacoresistant epilepsies, other investigations are helpful. One of them is PET, a functional interictal technique that can help us identify the onset of these seizures due to metabolic changes. SPECT is another functional but ictal investigation with preoperative guidance.

SPECT and PET imaging modalities play a vital role in the presurgical evaluation of patients with epilepsy, especially those with negative MRIs or multiple foci on EEG monitoring. Another essential feature is the assessment of the integrity of the rest of the brain tissue, which provides information about the possible pathogenesis of neurocognitive or behavioral disorders. It is important to note and underline that these are not diagnostic tools and should not be used to support a diagnosis of epilepsy.

The aim of these new imaging techniques, together with a multidisciplinary perspective on the presurgical assessment of patients with epilepsy, is to have increasingly better outcomes, with reduced post-surgical neurological deficits and improved quality of life.

The combination of structural and functional methods has been used in multimodal learning models to discover the seizure onset zone and assimilate the more accurate mechanisms involved in structural and functional abnormalities in a very often encountered pathology, i.e., epilepsy.

Abstract: *Burn injuries are among the most severe forms of trauma, often leading to multiple organ dysfunction syndrome (MODS), a major contributor to morbidity and mortality in burn patients. This review examines the pathophysiological mechanisms, clinical manifestations, and management strategies associated with MODS in burn patients. Following a severe burn injury, the systemic inflammatory response and subsequent release of pro-inflammatory cytokines precipitate dysfunction across various organ systems. Early recognition and aggressive management of MODS, including fluid resuscitation, infection control, and organ support, are crucial for improving survival outcomes. A comprehensive understanding of the multifactorial etiology and interrelated nature of organ dysfunction in burn patients is essential for developing targeted therapies and optimizing patient care. This review provides a current overview of the topic. In the coming years, new insights into the pathophysiological mechanisms are expected to enhance our comprehension of the subject further.*

Keywords: *burn injury, systemic inflammatory response, multiple organ dysfunction syndrome, cardiac dysfunction, respiratory dysfunction, acute renal failure, hepatic dysfunction, encephalopathy, coagulopathy, sepsis*

INTRODUCTION

Burn injuries are a major threat in military environments, historically present for over 5,000 years. Modern weapons have heightened the risk, causing significant casualties among soldiers and civilians. Advanced weapons, such as napalm, white phosphorus, anti-armor weapons, and fuel-air explosives, pose a high risk of causing severe burns. While protective gear like Kevlar vests has increased survival rates by protecting vital areas, exposed body parts still suffer from serious burns and shrapnel injuries. Advances in battlefield medical care have reduced the fatality rate of combat injuries, but severe burns remain complicated and require long-term treatment and rehabilitation. [1]

In the best circumstances, optimal treatment of war-related burn injuries can salvage about 50% of patients with burns covering 60-70% of their total body surface area (TBSA). Limited resources necessitate prioritizing care for those who will benefit the most, focusing on patients with burns covering 20-70% TBSA. In battlefield triage with resource constraints, patients with burns over 80% TBSA may receive palliative care, while those with burns of 20% or less and who are stable may have care delayed. Triage adjustments should consider coexisting inhalation or mechanical injuries, which reduce the treatment threshold by 10%. Burns on the hands, face, feet, and perineum may require increased care despite a lower TBSA burn percentage. [2]

Multiple organ dysfunction syndrome (MODS) is a severe complication in burn patients, particularly those with extensive burns. Severe burns trigger a systemic inflammatory response syndrome (SIRS), leading to widespread inflammation and potential organ failure. Extensive fluid loss from burn wounds can cause hypovolemic shock, impairing organ perfusion and function. Burn wounds are highly susceptible to infection, which can lead to sepsis and subsequent organ dysfunction. MODS significantly increases morbidity and mortality in burn patients, necessitating a multidisciplinary approach to manage and support affected organ systems effectively. [3-5]

In the early 1970s, Baue characterized the syndrome known as progressive or sequential multiple organ failure [6]. The term "multiple organ dysfunction syndrome" was introduced in 1991 during the Consensus Conference of the American College of Chest Physicians and the Society of Critical Care Medicine and it was defined as the presence of compromised organ function necessitating therapeutic interventions for maintaining homeostasis. The conference also addressed the systemic inflammatory response syndrome (SIRS) to delineate the clinical and paraclinical manifestations of systemic inflammation [7]. Later on, several scoring systems were devised to assess multiple organ dysfunction, including the MOD (Multiple Organ Dysfunction) score [8], the SOFA (Sequential Organ Failure Assessment) score [9], and the LODS (Logistic Organ Dysfunction) score [10], all based on the assessment of six parameters: respiratory, cardiovascular, hepatic, renal, neurological, and coagulation systems.

As the quality of medical care has improved, multiple organ dysfunction has become the leading cause of mortality associated with trauma in patients who survive the initial injury and are admitted to intensive care. The presence of multiple organ dysfunction is associated with increased morbidity and mortality in patients who have survived the first few hours after trauma [11].

PATHOPHYSIOLOGY OF MODS

The pathophysiology of MODS is multifactorial, complex, and still not fully understood. In the 1990s, multiple organ dysfunction was described as a bimodal phenomenon: the one-hit model and the two-hit model [12].

Currently, three models have been proposed to explain the occurrence of MODS:

- One-hit/one-event model: A massive trauma induces an intense SIRS associated with the onset of organ dysfunction.
- Two-hit/two-event model: Describes an initial injury followed by a second, seemingly minor injury that promotes inflammation and immunologic dysfunction. Thus, in the presence of moderate SIRS, a secondary activating event (such as surgical interventions, infections, embolism, transfusions) occurring during the compensatory anti-inflammatory response syndrome (CARS) will lead to late MODS
- Sustained injury model: Describes a continuous injury that acts both as the initial injury and maintains dysfunction [12-13].

Modern theories propose a system in which aggression simultaneously triggers two opposing responses: a pro-inflammatory response (SIRS) and an anti-inflammatory response (SARS, previously called compensatory, CARS), whose intensity and predominance correlate with the occurrence of MODS [14-15]. Early-onset multiple organ dysfunction is induced by the pro-inflammatory status with the activation of the immune system within SIRS, while late-onset multiple organ dysfunction is due to the exacerbation of anti-inflammatory responses within SARS, leading to immunosuppression, delayed healing, and increased susceptibility to infections [16].

There are several mechanisms implicated in the development of MODS, including mitochondrial dysfunction, alterations in immune system regulation, tissue or cellular hypoxia, activation of cellular apoptosis, and bacterial translocation from the gastrointestinal tract [17]. The factors involved in the development of MODS include:

- Persistent thrombocytopenia: It has been demonstrated that the interaction between platelets and neutrophils is involved in the development of acute lung injury (ALI), and antiplatelet therapies have been associated with a reduced risk of ALI, MODS, and decreased mortality in patients with adult respiratory distress syndrome (ARDS) [18].
- Polymorphonuclear leukocytes (PMNs): They act through local cytotoxic effects produced by PMN degranulation and the release of reactive oxygen species, nitric oxide, and pro-inflammatory mediators such as IL-6, IL-8, and TNF-α [19].
- Tissue macrophages and circulating monocytes [19].
- Pro-inflammatory cytokines (TNF-α, IL-1, IL-2, IL-6, IL-8, IL-17, MIP, GM-CSF, IFN-γ) and anti-inflammatory cytokines (IL-4, IL-10, IL-13) [20].
- The complement system: It is activated with the production of pro-inflammatory molecules C3a, C3b, and C5a, and the formation of the C5b-C9 complex, which leads to the lysis of the target cell. The activation of the complement system results in the production of reactive oxygen species, arachidonic acid metabolites, and cytokines [21-22].

In burn patients, it is considered that multiple organ dysfunction syndrome (MODS) is triggered by an inflammatory status, often associated, but not always, with sepsis. The onset of MODS can be caused either by extensive infection or by multiple infections with a smaller systemic impact, but which stimulate inflammation [23].

Other possible causes for MODS include:

- Gastrointestinal barrier impairment: involves bacterial translocation into the portal and lymphatic circulation, promoting the inflammatory response, or causing sepsis [24].
- Presence of uncovered burn wounds: leads to persistent inflammation and elevated levels of IL-6, IL-8, and TNF, contributing to a hypermetabolic and inflammatory status [25].
- Tissue hypoxia associated with hypoperfusion: causes cellular dysfunction through inadequate oxidative mechanisms and produces oxygen radicals [4].

In severely burned patients, MODS is the leading cause of death, with reported mortality rates in studies ranging from 29% to 86% [26-29]. The severity of MODS and mortality in burned patients correlate with the burned body surface area, the presence of deep burns, and the patient's age. The onset of MODS leads to prolonged hospitalization in intensive care, increased duration of ventilatory support, and longer hospital stays [26].

Burns over 30% of the body surface area induce a systemic inflammatory response associated with fluid loss through burn wounds and fluid extravasation into the interstitial space. This results in hypovolemia with hemodynamic changes similar to those seen in hemorrhagic shock, including decreased plasma volume, cardiac output, and urine output, as well as increased peripheral vascular resistance with decreased peripheral blood flow. These manifestations characterize post-burn shock, a particularly severe type of shock in severely burned patients, occurring primarily within the first 24 hours, peaking at 6-8 hours post-burn [31-32].

Inflammatory mediators, both local and systemic, involved in the pathogenesis of post-burn shock include histamine, TNF, interleukins, products of the arachidonic acid cascade (prostaglandins and thromboxanes), serotonin, bradykinin, nitric oxide, and oxygen radicals. Additionally, levels of certain hormones and cardiovascular function mediators are frequently elevated: epinephrine, norepinephrine, vasopressin, angiotensin II, and neuropeptide Y [33].

Similar to the treatment of other forms of hypovolemic shock, the main therapeutic objective is the prompt restoration of intravascular volume to preserve tissue perfusion. However, volume resuscitation in burns is complicated by the presence of edema not only in burned tissues but also in unburned tissues.

Consequently, large volumes of fluids are necessary to maintain intravascular volume in the initial hours following extensive burns [32]. Studies have shown that 50% of the edema fluid volume is found in unburned tissues [34].

RESPIRATORY DYSFUNCTION

Post-burn respiratory dysfunction is multifactorial, with the most common causes being the presence of inhalation injuries and the development of acute respiratory distress syndrome (ARDS) [35]. However, any pulmonary injury can be exacerbated by damage to the small airways (<2mm) and pulmonary alveoli induced by mechanical ventilation [36]. The evolution of respiratory dysfunction is also contributed to by the onset of pneumonia, which has an increased incidence, especially in patients with inhalation burns [37]. The presence of inhalation burns is a negative prognostic factor for morbidity and mortality, as established in the literature [38-39]. The severity of inhalation burns correlates with an increased need for tracheostomy, the number of days of mechanical ventilation, and a longer duration of hospitalization in intensive care [40]. In association with cutaneous burns, the presence of inhalation injuries increases the volume requirements for fluid resuscitation of burn patients and leads to a higher incidence of pulmonary complications [41].

From the perspective of affected structures and the etiopathogenic mechanism, inhalation injuries are divided into three categories:

1. Thermal injury to the upper airways: This results directly from elevated temperatures and consists of edema in the supraglottic structures and obstruction of the upper airways within the first few hours post-burn.

2. Chemical irritation of the lower airways: This is caused by the presence of toxic chemical compounds (such as sulfur dioxide, nitrogen dioxide, ammonia, cyanides, and aldehydes) in smoke, that cause epithelial and capillary endothelial damage to the respiratory tract, with histological features similar to tracheobronchitis. Physiopathological changes include increased local blood flow in the bronchi, local exudate and bronchiolar edema, necrotizing bronchitis, impaired mucociliary clearance with decreased bacterial removal, alveolar collapse, and atelectasis due to surfactant loss, activation of local macrophages with inflammatory response, bronchospasm, and increased capillary permeability leading to enhanced pulmonary edema. After smoke exposure, respiratory failure may occur due to airway obstruction from epithelial detritus, fibrin clots, and mucus within a variable timeframe, from 12 hours to 2 days post-burn.

3. Systemic injury: This occurs through the inhalation of carbon monoxide (CO) or cyanides, which causes both pulmonary effects, such as hypoxia and hypercapnia, and systemic effects mediated by pro-inflammatory cytokines. [41-44].

Acute respiratory distress syndrome (ARDS) is characterized by severe hypoxemia in the context of pulmonary alveolar damage, progressing to acute pulmonary edema and acute respiratory failure [45]. In burn patients, ARDS can occur either in association with airway burns or in their absence due to the systemic inflammatory response associated with burns during the post-burn shock period or septic complications of burns following the post-burn shock period. Inhalation injuries are an independent risk factor for the development of ARDS, with earlier onset and greater severity compared to ARDS induced by cutaneous burns [46]. The severe form of ARDS with refractory respiratory failure is a significant cause of death in severely burned patients [47].

CARDIAC DYSFUNCTION

Cardiac dysfunction leads to organ hypoperfusion, peripheral microcirculation damage, burn wound expansion, and decreased resistance of burned wounds to bacterial infection [48-49]. Cardiac failure is one of the main causes of mortality in severely burned patients within the first two days post-burn [50]

In the first 24-48 hours after a burn, corresponding to the ebb phase, there is a decrease in myocardial contraction and cardiac output [51]. The reduction in cardiac contractility has been associated with cardiomyocyte apoptosis within the first 48 hours post-burn, particularly affecting cells in the subendocardial tissue of the left ventricle [52]. Increased capillary permeability leads to a reduction in circulating plasma volume and an increase in peripheral vascular resistance. Some authors have considered hypovolemia as the primary factor responsible for reduced cardiac output in the early post-burn period [53]. Others have suggested that elevated levels of serum catecholamines, vasopressin, angiotensin II, and neuropeptide Y are responsible for inducing cardiovascular dysfunction, even in the absence of hypovolemia [49].

Data from the literature showed that hypovolemia can persist despite aggressive fluid resuscitation and in the absence of routinely monitored signs of hypoperfusion, such as decreased urine output and decreased mean arterial pressure [51]. Studies have demonstrated that serum lactate levels or the base deficit (the sum of lactate and other acidic metabolites released in the presence of tissue hypoxia) correlate better with the severity of hypoperfusion and remain elevated during fluid resuscitation, even when urine output and blood pressure are adequate [49,54]

From the third day post-burn, corresponding to the flow phase, myocardial contractility improves, and tachycardia and increased metabolic demands with increased catabolism appear [55]. The association of inhalation injuries can further cause right ventricular dysfunction through increased resistance in the pulmonary arteries and pulmonary hypertension, increasing the afterload of the right ventricle [56]. Consequently, left ventricular dysfunction can occur either as global heart failure or due to the displacement of the interventricular septum towards the left ventricle due to increased right ventricular filling [49,57].

Cardiac dysfunction is associated with increased mortality during hospitalization and persistent elevated serum catecholamine levels, tachycardia, and increased oxygen consumption continuing up to two years post-burn [49,58]. Studies in the literature have concluded that sepsis contributes to already present cardiac dysfunction in burn cases [59].

RENAL DYSFUNCTION

Another significant complication in the progression of burn patients is acute kidney injury (AKI), which may manifest either early after the burn injury or later, concurrent with the development of sepsis and in conjunction with other organ dysfunctions [60]. AKI is characterized by a sudden reduction in glomerular filtration with the kidneys' inability to maintain fluid and electrolyte balance, with the first clinical and paraclinical signs being decreased urine output and a subsequent increase in serum creatinine and urea [61]. The incidence of acute renal failure in burn patients has decreased following advancements in the treatment of cardiovascular dysfunction [60].

The causes of early acute renal failure are multiple:

- Myocardial depression: causes decreased cardiac output and renal hypoperfusion [63]

- Hypovolemia and renal hypoperfusion due to underestimation of fluid requirements during fluid resuscitation or delayed fluid resuscitation [62]. Renal hypoperfusion is followed by renal tubular necrosis [63]

- Hemolysis: free hemoglobin can precipitate in renal tubules or cause damage to the tubular epithelium [64]

- Rhabdomyolysis: increased serum levels of myoglobin in extensive deep burns, electrocutions, and compartment syndromes lead to myoglobinuria with myoglobin precipitation in renal tubules, vasoconstriction of afferent arterioles, and production of oxygen free radicals [65]

- Renal hypoperfusion: through increased levels of catecholamines, angiotensin II, aldosterone, and vasopressin, and reduced atrial natriuretic peptide [66]

- Inflammatory mediators such as TNF, IL1, prostaglandins, leukotrienes, thromboxane, and platelet-activating factor: released early post-burn, causing renal tissue damage and microthrombi in renal glomerular capillaries [66]

- Use of nephrotoxic medications, such as aminoglycoside antibiotics, nonsteroidal anti-inflammatory drugs, barbiturates, and hydroxocobalamin [67]

- Respiratory dysfunction: through reduced oxygen supply to the kidneys [68]

Early acute renal failure is usually reversible [252]. Late renal injury typically occurs within the syndrome of multiple organ dysfunction, often associated with severe sepsis. The etiology of acute renal failure in sepsis is also multifactorial, caused by renal arteriole vasoconstriction (prerenal cause), a procoagulant status that induces disseminated intravascular coagulation (DIC), and micro-thrombosis in renal glomeruli and the endothelial damage [67]

Prevention of renal failure is based on monitoring renal function, correcting hypovolemia, hypoxia, and acidosis, limiting nephrotoxic medications, administering thromboprophylaxis in the context of procoagulant status, and early excision-grafting of post-burn lesions to prevent wound infection and sepsis [69].

HEPATIC DYSFUNCTION

Liver injury following burns occurs via multiple mechanisms such as decreased hepatic blood flow, portal hypertension due to the action of endotoxins, release of hepatotoxic products from burn wounds, intrahepatic cholestasis, programmed cell death of hepatocytes through ischemia-reperfusion mechanisms, decreased hepatic blood flow, and the action of proinflammatory cytokines IL1 and TNF-α and hepatic dysfunction due to sepsis from pathogenic microorganisms, toxins, and inflammatory mediators [70-72].

Major burns lead to transient increases in levels of aspartate aminotransferase, alanine aminotransferase, and alkaline phosphatase, in up to 50% of cases, which typically resolve spontaneously without significant clinical impact [73]. Less frequently, there may be an increase in serum bilirubin, which, however, implies more severe consequences. Severe and persistent increases in liver enzymes, especially bilirubin, often indicate burn-associated complications such as sepsis and are associated with a poor prognosis [74].

During the acute phase response in severely burned patients, there is an increase in the production of acute phase proteins (α1-acid glycoprotein, C-reactive protein, haptoglobin, and α1-antitrypsin) along with a decrease in the levels of constitutive hepatic proteins (prealbumin, transferrin, retinol-binding protein). [75] In the context of meeting the nutritional needs of patients, the decrease in constitutive hepatic proteins is due more to decreased hepatic synthesis and expression. Proinflammatory cytokines such as IL-1β, IL-6, TNF-α, IL-8, and IL-10 act as mediators of the acute phase response and increase immediately post-burn, with their levels remaining elevated for a long time after injury. The uncontrolled and prolonged action of proinflammatory cytokines and acute phase proteins can lead to hypermetabolism and catabolism, which result in multiple organ failure, significantly increasing both morbidity and mortality rates [75-77].

Liver damage has been associated with the development of hepatic edema, with the liver significantly increasing in weight within 2 to 7 days post-burn and reaching a maximum size at 2 weeks post-injury. At 12 months, liver weight can still be increased by 40 to 50% compared to predicted weight [75,78].

Manifestations of liver dysfunction in burns include:

- Hypoalbuminemia due to decreased albumin synthesis; hypoalbuminemia leads to worsening edema and delayed wound healing

- Coagulopathy: due to impaired synthesis of coagulation factors in the liver, increasing the risk of bleeding

- Hyperbilirubinemia

- Glucose metabolism disorders due to impaired hepatic gluconeogenesis and glycogen storage; hyperglycemia is often observed due to deficient glycogenesis and insulin resistance, while hypoglycemia can occur in severe liver failure cases where gluconeogenesis is profoundly affected

- Hepatic steatosis due to altered lipid metabolism

- Sepsis: impaired liver function influences the immune response, making burn patients more susceptible to infections and sepsis [73,75,79].

NEUROLOGIC DYSFUNCTION

Post-burn encephalopathy is defined as acute neurological dysfunction following burns, independent of iatrogenic factors. Patients with post-burn encephalopathy exhibit seizures, agitation, hallucinations, delirium, and other neurological disturbances [80].

Morphopathological studies have demonstrated significant pathological changes in the brain, including massive edema leading to herniation, diffuse intraparenchymal hemorrhage, cerebral infarcts, metabolic encephalopathies, pontine demyelination, infectious complications such as meningitis, cerebral microabscesses, and septic emboli [81-82].

Cerebral ischemia, often underestimated, is a frequent cause of post-burn encephalopathy and is primarily due to hypovolemia associated with severe burns. Hemorrhagic cerebral complications are less common than ischemic ones and present as multiple subarachnoid hemorrhages in both the brain and spinal cord. In patients without hypoxia and hemodynamic disturbances, hemorrhages are more frequently associated with inhalation injuries than with cutaneous burns [83-84].

Proinflammatory cytokines such as TNF-α, IL-1β, and IL-6, along with reactive nitrogen species and oxygen-free radicals released from burned tissues, can alter the integrity of the blood-brain barrier. These molecules, along with neutrophils, can reach the brain, causing microglial cell activation and neuronal apoptosis. The activation of microglial cells in the brain and spinal cord leads to a local inflammatory response and neuronal apoptosis. Activated neutrophils, once they reach the central nervous system, release proteases, oxygen free radicals, reactive nitrogen species, and cytokines, further amplifying the inflammatory process [85].

HEMATOLOGIC DYSFUNCTION

Causes of burn-associated coagulopathy include a systemic inflammatory response with massive cytokine release that interferes with normal coagulation, tissue damage causing direct blood vessel injury and tissue factor release, activating the extrinsic coagulation pathway, impaired normal platelet function, hypoperfusion leading to hypoxia and acidosis, consumption of coagulation factors through clot formation, increased fibrinolytic activity in response to clots and iatrogenic factors (fluid resuscitation and associated hemodilution, as well as blood losses from surgical excision and grafting) [86-87]. Disseminated intravascular coagulation (DIC) is also part of the spectrum of coagulopathy in burn patients. DIC is a clinical-biological syndrome characterized by uncontrolled systemic activation of coagulation, with risks of micro- and macrovascular thromboses and progressive consumptive coagulopathy, increasing the risk of bleeding. [88].

In burn patients, sepsis-induced coagulopathy may also occur, ranging from subclinical coagulopathy to fulminant DIC. [89] Septic patients exhibit a prothrombotic status due to activation of the extrinsic coagulation pathway, amplification of the cytokine-induced coagulation cascade, reduced fibrinolysis, and suppression of natural anticoagulant pathways [90].

Hypercoagulability in burn patients is associated with an increased risk of thromboembolic complications (deep vein thrombosis and pulmonary embolism), with incidence rates in studies ranging from 0.2% to 25% [91]. Contributing factors include patient-specific predispositions (genetic thrombophilia or comorbidities such as cancer history, atherosclerosis, heart failure, chronic kidney disease, previous thromboembolic episodes), iatrogenic factors (presence of central or peripheral venous catheters, repeated venipunctures, certain medications), and the lack of mobilization, serial surgical interventions, and long operative times [92]

Preventive and management measures for coagulopathy in burn patients include general supportive measures such as avoiding dilutional coagulopathy and preventing hypothermia, as well as targeted therapeutic measures like blood product transfusion or antithrombin administration [93].

INFECTIONS IN BURN PATIENTS

The destruction of the skin barrier, as well as the decrease in local cellular and humoral immune responses, predisposes patients with severe burns to an increased risk of infectious complications. Infections can progress to sepsis, septic shock, and multiple organ dysfunction syndrome, and are one of the main causes of morbidity and mortality, accounting for 42-65% of deaths in severely burned patients. [94-95]

The burned wound in deep partial-thickness burns and full-thickness burns is a protein-rich and avascular environment, representing an ideal area for the colonization and proliferation of germs. The lack of vascularization of the post-burn eschar opposes the migration of immune cells to this area and decreases the local availability of systemically administered antimicrobial therapy, while the toxic substances released from the eschar decrease the local immune response. [96] The burned wound is susceptible to colonization with exogenous or endogenous opportunistic microorganisms. Depending on factors such as the patient's age, the burned surface area and burn depth, the type and number of microorganisms, and the production of enzymes and toxins, invasive infections of the burned wound may occur. [97]

Burn patients can be colonized with multiple germs, often resistant to antibiotics, without showing perilesional erythema or cellulitis. In contrast, invasive infections are characterized by the presence of cellulitis in the surrounding tissues, deepening of the burn wounds, debridement of the eschar, or the appearance of necrotic areas. Patients may become febrile or exhibit elevated inflammatory markers, but these clinical and paraclinical signs are difficult to differentiate from those associated with the inflammatory response in severe burns. [94]

According to The Third International Consensus Definitions for Sepsis and Septic Shock (Sepsis-3), sepsis is defined as life-threatening organ dysfunction caused by a dysregulated host response to infection. For practical application, organ dysfunction is represented by an increase of 2 or more points in the SOFA score, which is associated with in-hospital mortality greater than 10%. Septic shock is defined as a subset of sepsis in which underlying circulatory, metabolic, and cellular abnormalities are profound enough to substantially increase mortality compared to sepsis without shock. The diagnosis of septic shock corresponds to the need for vasopressor support to maintain a mean arterial pressure above 65 mmHg and an increase in serum lactate levels above 2 mmol/L, in the absence of hypovolemia. [98]

Burn patients exhibit the clinical and paraclinical signs of SIRS even in the absence of sepsis, which has led to the necessity of identifying other diagnostic methods for sepsis. At a consensus conference of the American Burn Association, an attempt was made to establish specific criteria for the diagnosis of sepsis in burn patients. [99] Sepsis should be suspected in the presence of a documented infection and clinical and paraclinical criteria, which are described in Table I.

Table 1: American Burn Association sepsis in burns criteria

At least 3 of the following criteria:	Documented infection:
Temperature >39°C or <36.5°C	Positive culture results
Heart rate >110 bpm	Identification of the pathogen through tissue biopsy
Respiratory rate >25/min in spontaneously breathing adults or Minute respiratory volume >12 L/min in mechanically ventilated adults	Clinical response to antimicrobial treatment
Thrombocytopenia <100,000/µl (considered after more than 3 days from the onset of initial resuscitation)	
Hyperglycemia >200 mg/dl in the absence of pre-existing diabetes mellitus or Insulin resistance is defined as an insulin requirement of more than 7 IU/hour continuous infusion or an increase of more than 25% in insulin requirement over 24 hours	
Inability to administer enteral nutrition for more than 24 hours due to: - Intolerance to enteral nutrition (gastric residual volume twice the volume of administered nutrition) - Uncontrolled diarrhea (more than 2500 ml/day in adults) - Abdominal distension	

In a meeting of experts, Dupuy and colleagues described the characteristics of the ideal biomarker, which should fulfill multiple roles: identifying high-risk patients, stratifying patients based on individual risk factors, and guiding therapeutic management. Thus, an ideal biomarker should be inexpensive, rapid, non-invasive, easily accepted by the patient, routinely available, and should combine diagnostic characteristics (including differentiating between non-infectious SIRS and sepsis, and between bacterial and viral infections) with prognostic characteristics (including mortality prediction) and the ability to evaluate treatment efficacy. [100]

This ideal biomarker has not been established, but inflammatory markers analyzed in studies for identifying sepsis in burn patients include C-reactive protein, procalcitonin, erythrocyte sedimentation rate, presepsin, serum TNFα, interleukins 6, 8, and 10, serum leukocyte levels, serum platelet levels, and serum lactate levels. [101-102]

With the development of burn centers, advances in the fluid resuscitation of patients with severe burns, and the promotion of early excision and grafting of burn wounds, the past trend of early death due to post-burn shock has now shifted to mortality due to infections and sepsis following prolonged hospitalizations. Preventing sepsis is a primary objective in severely burned patients. Several measures have been proposed to reduce the risk of infectious complications. Early excision of burn wounds and coverage with skin grafts reduce bacterial colonization of burn wounds, decrease the release of inflammatory mediators and the incidence of SIRS, and reduce the risk of sepsis and multiple organ dysfunction. [103-104]

In severely burned patients, some succumb early due to the severity of their burns, while others die after prolonged hospitalization complicated by the development of numerous complications. Multiple organ dysfunction syndrome (MODS) associated with sepsis is the leading cause of death in patients who survive early post-burn shock. [27-28]

The risk factors for the development of sepsis in severely burned patients include:

- Total body surface area (TBSA) burned
- Extreme ages
- Pre-existing conditions accompanied by immune-suppression: diabetes, renal or hepatic pathologies, AIDS, malignancies
- Presence of uncovered burn wounds

- Use of urinary catheters, venous and arterial catheters, or mechanical ventilation [105-106]

A particularly concerning group of bacteria in the context of major burns due to their notorious ability to evade standard antibiotic treatments and develop resistance to last-line antibiotics are the ESKAPE pathogens, comprising Enterococcus faecium, Staphylococcus aureus, Klebsiella pneumoniae, Acinetobacter baumannii, Pseudomonas aeruginosa, and Enterobacter spp. [107]

In patients suspected of having sepsis, a thorough search for a probable source should be conducted; clinical symptoms and signs, appropriate microbiological cultures, and relevant imaging techniques should be used to try to determine the infectious source. Antimicrobial medication should be administered early and not delayed until culture data are obtained. Broad-spectrum antibiotic therapy, preferably a combination of antimicrobials, should be administered to cover all suspected germs based on the probable source of infection, local microbiological flora, and specific intensive care flora. After obtaining culture results, antibiotic therapy should be reassessed and de-escalated, narrowing the spectrum to optimize treatment efficacy, limit toxicity, prevent the emergence of multidrug-resistant germs, and reduce treatment costs. [108-109]

CONCLUSIONS

Understanding these mechanisms and pathological findings is crucial for managing and preventing complications in burn patients. Early intervention and vigilant monitoring are essential for mitigating the risks associated with severe burns and reducing the incidence of multiple organ dysfunction syndrome. By recognizing the systemic inflammatory responses, fluid loss, and potential for infection that accompany severe burn injuries, healthcare providers can implement targeted strategies to support organ function, prevent sepsis, and optimize patient outcomes. Continuous advancements in burn care and precise triage and treatment approaches are vital for improving survival rates and ensuring better long-term recovery for burn patients. This is a current overview of the subject. In the coming years, new information on the pathophysiological mechanisms will likely emerge to complete the level of understanding on the subject.

Abstract: *Due to the frequent occurrence of international military conflicts, there has been an increasing number of soldiers who have suffered injuries and disabilities. The soldiers' disability is a crucial factor influencing combat effectiveness. Objective: This study aims to investigate the current situation of military disability and its influencing factors to provide a basis for reducing the rate of military disability. A total of 430 Chinese military disability assessment materials from 2021 were collected retrospectively between April 2023 and September 2023. The data on injuries, illnesses, and disabilities of soldiers were subjected to statistical analysis with informed consent, and personal information was anonymized to ensure privacy. The occurrence of disability was analyzed based on gender, rank, and different disability systems using unifactor analysis and multiple linear regression analysis. Statistical differences (P<0.05) were found in the degree of disability among soldiers of different ages, status categories, nature of disabilities, disability systems, and causes of disabilities. Age, status category, nature of disabilities, disability systems, and causes were identified as the main factors affecting the degree of soldiers' disabilities, with a total explanation rate of 58.3%. Injuries to the motor system during training were identified as the primary cause leading to soldier disabilities. In conclusion, this study shows that it is essential to prioritize protection against training injuries to minimize soldier disabilities.*

Keywords: *soldier; disabilities; influencing factors; investigation*

INTRODUCTION

Soldiers are the primary component of the national defense force, responsible for safeguarding national security, protecting and defending national borders, maintaining social stability, and other related duties. The physical and mental well-being of soldiers is directly linked to their combat effectiveness, with disability being a major factor affecting this during peacetime operations [1]. The effects of military activities on soldiers include not only physical aspects but also psychological aspects [2].

Previous research has indicated that the impact of military operations on soldiers is irreversible, with some individuals experiencing lasting effects such as physical disabilities [3,4,5,6], pain [7], hearing loss [8], blindness [9], post-traumatic stress disorder (PTSD) [10], traumatic brain injury (TBI) [11], and fractures [12,13]. Data from the US Army, Navy, and Air Force disability agencies [14] show that 10 to 30 out of every 1000 soldiers are disabled each year. However, only 30% of these cases are due to pre-existing conditions; the majority result from injuries sustained during military operations.

The American Veterans Benefits Administration offers disability benefits to individuals and service members who previously served full-time active military duty and were discharged generally or honorably [15]. These benefits can be categorized into three types based on the causes of disabilities: (1) Service-connected disability, which refers to a disability resulting from direct injury or disease while on active duty; (2) Nonservice-connected disability, which is attributed to an injury not acquired during active duty; (3) Presumptive service connection, which encompasses various chronic conditions that appear within 1 year after discharge from active duty.

In China, military training is a significant contributing factor to physical disabilities among soldiers [16]. Research has indicated that the incidence of military training injuries in the new recruit population in China is 21.04%, suggesting that one out of every five individuals will experience a military training injury [17]. Therefore, this study conducts a cross-sectional investigation to analyze the occurrence and influencing factors of disability among Chinese military personnel, to enhance the effectiveness of prevention and treatment of military training injuries.

MATERIALS AND METHODS

Research objects

A total of 430 Chinese military disability assessment materials from 2021 were collected retrospectively between April 2023 and September 2023. The data on injuries, illnesses, and disabilities of soldiers underwent statistical analysis with consent, and personal information was anonymized to ensure privacy. The disability assessment materials included 400 males and 30 females, with an average age of 30.75 ± 7.38 years.

Research methods

According to the "Military Disability Rating Standards"[17], injuries, illnesses, and disabilities of officers and soldiers were graded on a scale from one to ten. A lower rating indicated a more severe injury or disability.

The classification of the causes of disability includes two aspects: (1) Disability due to service, which refers to disabilities directly caused by participating in work or military activities during active duty; (2) Non-service related disability, which refers to disabilities caused by illness during active duty due to physical reasons. The data from disability assessment materials were entered into the computer and checked by two individuals to ensure accuracy.

Inclusion criteria: the disability condition meets the Chinese Military Disability Assessment Standards and is eligible for disability assessment [17], disability assessment standards are mainly based on the site of injury, severity and sequelae to determine the level of disability. Other conditions were excluded from this study, such as cases where recovery after injury was good, and there were no obvious functional abnormalities.

Classifying and analyzing the levels of disability in different groups based on the disability assessment materials. This study was conducted in accordance with the Declaration of Helsinki and approved by the Ethics Committee of The Strategic Support Force Military Center (LS202203, Approved:2022-10-27).

Statistical Methods

Statistical analysis of the data was conducted using SPSS 22.0. Descriptive statistics were used to represent continuous variables as mean and standard deviation and categorical variables as rates or proportions. The data was categorized based on patient medical records, and chi-square tests and multiple linear regression analysis were performed with a significance level set at P<0.05.

RESULTS

The basic situation of disability assessment of military personnel in 2021

In 2021, a total of 430 disability assessment materials submitted to a certain Ministry met the military standards for disability assessment.There were 2 cases (0.5%) of Level 1, 1 case (0.2%) of Level 2, 2 cases (0.5%) of Level 3, 2 cases (0.5%) of Level 5, 31 cases (7.2%) of Level 6, 4 cases (0.9%) of Level 7, 109 cases (25.3%) of Level 8, 175 cases (40.7%) of Level 9, and 104 cases (24.2%) of Level 10.

Statistical differences were observed among different grades of disability in different age groups, status categories, and the nature of disability, as shown in Table 1.

Grade distribution of disability in different disability systems

In 2021, the majority of cases (90.9%) were related to motor system disability, followed by 4.9% of neurological disability cases and 1.4% of urinary disability cases, and were statistically differentiated by examination (P<0.01). See Table 2 for more details.

Table 2: Comparison of disability among soldiers with different physiological systems

Disability systems	Disability Grade									Total
	Level 1	Level 2	Level 3	Level 5	Level 6	Level 7	Level 8	Level 9	Level 10	
Respiratory System	0	0	0	0	0	0	0	0	1 (0.2%)	1 (0.2%)
Urinary System	0	0	0	0	3 (0.7%)	0	2 (0.5%)	0	1 (0.2%)	6 (1.4%)
Endocrine System	0	0	1 (0.2%)	0	4 (0.9%)	0	0	0	0	5 (1.2%)

χ2=391.947, P<0.01, χ2 for chi-square tests.

Grade distribution of disability caused by different causes

In 2021, the majority of injuries (71.9%) occurred during daily training, followed by 12.1% during exercise and training, and 7.9% due to illness, and were statistically differentiated by examination (P<0.01). See Table 3 for more details.

Multi-factor analysis of the influencing factors of a soldier's assessment of disability

Multiple linear regression analysis was conducted to examine the relationship between disability rating and various independent variables that showed statistical significance in univariate analysis (see Table 4 for assigned values). The findings revealed that the nature of disability, identity category, age, disability system, and cause of disability were the primary factors influencing the degree of disability (F=121.185, P<0.01). The overall explanatory power of these variables was 58.3%, as presented in Table 5.

Table 4: Argument assignment method

Variables	Assignment method
Gender	Male = 1, Female = 2.
Age	Original value input.
Identity category	Conscript = 1, Noncommissioned Officer = 2, Officer = 3.
Disabling Character	Non-service = 1, Service = 2.
Disabling System	Respiratory System = 1, Urinary System = 2, Endocrine System = 3, Nervous System = 4, Digestive System = 5, Circulatory System = 6, Motor System = 7, Blood System = 8.
Causes of Disability	Illness = 1, Traffic Accident = 2, Physical Activity = 3, Daily Training = 4, Exercise and Training Tasks= 5, Other = 6.

DISCUSSION

In 2021, the majority of soldiers' disabilities were concentrated in grades 8 to 10 (90.2%). This finding is consistent with the research results of Wang [19] and Li [20], indicating that most soldiers injured during normal work experience moderate to low levels of disability, with fewer cases of severe disability. This may be attributed to a greater emphasis on safety measures during peacetime work, more effective preventive measures against major safety accidents, and successful implementation of the safety form analysis system [21,22,23].

In the analysis of the disability system, it is evident that soldiers' disabilities are primarily related to sports activities, with a concentration of disabilities falling within the 8 to 10 level. The causes of these disabilities can be attributed to daily training, and factors such as the nature of the disability, identity category, and age have an impact on the severity of the disability. This pattern is similar to that observed in Chinese Air Force soldiers [24]. In 2020, certain departments under the Central Military Commission made adjustments to the "Military Physical Training Outline", resulting in an increase in training-related injuries due to heightened difficulty levels [25]. Furthermore, young soldiers' competitive spirit often leads them to neglect their physical well-being during training sessions, making them susceptible to injuries or fatigue. Disabilities resulting from training missions are typically linked to officers and soldiers having lax attitudes towards prevention measures and non-standard equipment operation due to psychological tension. Pang [26] also argues that military training missions' high physical load and tension are primary contributors leading to bodily harm, physiological fatigue, and potentially severe consequences.

Methods to Improve the Condition of Injured Soldiers

1. Comprehensive Preventive Measures

In recent years, training organizations at all levels have increasingly prioritized the prevention of various types of training injuries. Despite these efforts, training injuries continue to be the leading cause of military disability. Therefore, it is crucial to strengthen protection in the following areas.

1.1. Pre-training preparation

Proper pre-training preparation is crucial in reducing the occurrence of training injuries. Engaging in warm-up activities can enhance the body's flexibility, adaptability, and malleability, thereby improving its ability to withstand high-intensity training. Furthermore, it can increase blood flow redistribution and velocity in the body, thus reducing the risk of injury to the musculoskeletal system. Additionally, providing comprehensive instruction in operational or action skills is essential for skilled athletes to prevent individual injury.

1.2. Moderation in training is essential

Moderate training plays a key role in preventing physical injuries. It is important for individuals to recognize their own limitations and for training organizations at all levels to consider each individual's body capacity when designing training programs. Gradually increasing the intensity of training can also help avoid injuries caused by overexertion during cross-training activities.

1.3. Post-training recovery

The post-training recovery stage is a critical factor in individual energy and power storage. Following high-intensity training, soldiers often experience exhaustion. Effective recovery can facilitate the body's recuperation and growth, ultimately enhancing soldiers' resilience to future training sessions.

2. Enhance organizational structure and management

Scientific training and program-based organization are fundamental principles for conducting military training. Training and exercise departments at all levels should enhance the planning of various types of training, organize tasks rationally and scientifically, and continuously improve soldiers' physical fitness while enhancing combat effectiveness. It is essential to maintain existing combat effectiveness standards while improving overall combat readiness. When implementing operational actions, organizers should consider operational processes, standards, and proficiency skills to avoid inexperienced individuals operating alone, which could lead to security risks.

Rigorously enforce the annual physical examination system

A well-organized arrangement of officers and soldiers participating in the annual military physical examination task can lead to early detection, diagnosis, and treatment of asymptomatic diseases. This proactive approach helps prevent permanent functional loss such as dysfunction, significantly reducing the disability rate among soldiers.

Limitations and Generalizability

This study is based on a sample of 430 disability assessment materials, which were the result of collaborative efforts from all our researchers. However, it should be noted that these materials may not fully represent all disability assessment outcomes in 2021, thus limiting the generalizability of our results. Additionally, there was a skewed gender ratio in our study with only 30 females compared to 400 males, even though the number of males in the military far exceeds that of females. This imbalance may have impacted the accuracy of our findings regarding gender differences.

Nevertheless, it is important to highlight that this study was able to capture some aspects of disability assessment among Chinese soldiers in 2021. By analyzing the causes of disability among 430 soldiers, we are still able to provide valuable recommendations for preventing disabilities within this population.

CONCLUSIONS

This study adopts the method of cross-sectional investigation to investigate the factors affecting the disabled status of Chinese soldiers. We found that age, rank category, nature of disability, involvement system and cause of disability were the main factors affecting the degree of disability in military personnel. Injury to the musculoskeletal system during training is the main cause of military disability. The prevention and treatment of training injuries is a very important research topic that can provide better health protection for soldiers. Therefore, coaches and managers at all levels need to pay attention to injury prevention in the training process, which can minimize the occurrence of military disabilities.

Conflicts of interest and sources of funding

The authors declare no conflict of interest, and this research has received no external funding.

Acknowledgments

This study has received support from relevant units of the Chinese People's Liberation Army, and we express our gratitude to Mr. DU for his invaluable assistance.

Authors' contribution

The initial draft was prepared and revised by LS, while FR and SX contributed by proposing hypotheses and preparing the dataset. QS further refined the analysis and provided crucial support for the manuscript. DNL, XG, SX, and YW conducted data collection in various units and offered theoretical support. LS and QS supervised all aspects of the study, including hypothesis formulation, design of data analysis plan, oversight of data analysis process, verification of results, and development of the manuscript based on the initial draft. All authors participated in reviewing and finalizing the manuscript which has been read and approved by everyone involved.

Ethics approval and consent to participate

The study was conducted in accordance with the Declaration of Helsinki, and approved by the Ethics Committee of Strategic Support Force Military Center (LS202203,2022.01.01).

Patient consent for publication

Written informed consent has been obtained from the patient (s) to publish this paper

Abstract: *Gestational diabetes (GDM) is characterized by the initial onset of elevated glucose levels while pregnant throughout the 24th week up until the 28th week of gestation affecting around 21.1 million live births in 2021. GDM is related to significant prolonged health risks for the mother and the unborn baby. A comprehensive research of the PubMed database was conducted between April and June 2024. As a response to IR, maternal beta cells increase in number and ramp up insulin production and release to sustain glucose balance. Physiological IR during pregnancy is driven by hormonal and inflammatory changes. Multiple risk factors contribute to the occurrence of GDM. Glycemic targets during pregnancy are more stringent than those for nonpregnant women. GDM can lead to several short-term or long-term complications during pregnancy for both the mother and the unborn baby. The first step in managing GDM involves lifestyle modifications. The next step in managing GDM involves the use of medication and insulin is the preferred pharmacological treatment. However, there are still many steps to be taken towards establishing an international prevention strategy and accurately determining the mechanisms involved in the development of GDM.*

Keywords: *gestational diabetes; pregnancy; placental hormones; gestational treatment*

INTRODUCTION

Gestational diabetes mellitus (GDM) is characterized as the initial onset of elevated glucose levels while pregnant, typically throughout the 24th week up until the 28th week of gestation. GDM has appeared among many prevalent pregnancy complications, with the rate of occurrence increasing in recent years [1]. The International Diabetes Federation (IDF) specifies that GDM affected around 21.1 million live births in 2021, with a higher prevalence noticed in low- and middle-income countries, where hyperglycemia during pregnancy is more common [2]. More recently, the term “early” gestational diabetes (early GD) has been used to define elevated glucose levels occurring before twenty weeks of pregnancy, and its prevalence is expected to be between 0.7% and 36.8% [3]. The term “late” gestational diabetes (late GD) is defined as elevated glucose levels between 24 to 28 weeks of gestation [4].

The history of diabetes in pregnancy dates back to 1824 when it was first described by Bennewitz [5]. The initial diagnostic criteria for this condition were proposed by Williams in 1909 [6]. Over time international organizations, including the World Health Organization (WHO), the International Association of Diabetes and Pregnancy Study Group (IADPSG), the Canadian Diabetes Association (CDA), and the American Diabetes Association (ADA) have developed guidelines outlining the diagnosis and screening for GDM [7].

GDM is related to significant prolonged health risks for the mother and the unborn baby. Pregnant women diagnosed with GDM face about 8-fold high risk regarding the possibility of developing type 2 diabetes (T2D), especially in the first 5-10 years postpartum [8]. Additionally, GDM can result in a variety of pregnancy complications, including fetal anomalies, spontaneous abortion, fetal demise, preeclampsia, macrosomia, neonatal hyperbilirubinemia, and hypoglycemia [9].

METHODS

A comprehensive research of the PubMed database was conducted between April and June 2024. Keywords used in the search included "gestational diabetes", "prevalence", "hyperglycemia", "risk factors", “diagnosis”, "placental hormones", "mechanism", and “treatment” as well as various combinations of these terms. The research was restricted to studies published in English. Exclusion criteria included studies that identified GDM diagnosis solely by codes, studies focusing on specific populations (e.g., by age, species, or race), and publications in the form of abstracts, letters, or case reports.

DISCUSSIONS

Etiopathogenesis

Insulin is secreted by pancreatic beta cells and plays a vital role in promoting glucose utilization by peripheral cells, decreasing glucose synthesis within the liver, and regulating lipid release from fat stores. When regular levels of insulin fail to obtain the desired response from insulin receptors, insulin resistance (IR) can develop. To compensate, the pancreatic beta cells must release more insulin to ensure glucose levels remain normal, leading to IR [10]. This process is a natural aspect of a healthy pregnancy, induced through placental hormones to guarantee that the unborn baby obtains sufficient essential nutrients for optimal development. As a response to IR, maternal beta cells increase in number and ramp up insulin production and release to sustain glucose balance [11].

GDM’s underlying mechanisms remain unclear, but it is believed that it results from the maternal pancreas's inability to adapt to the increase of insulin demand during pregnancy, leading to hyperglycemia [12,13]. The placenta seems to play a crucial role in GDM formation, as several studies have explored the physiological mechanisms involved.

Physiological IR during pregnancy is driven by hormonal and inflammatory changes [14]. Metabolic changes also occur, with IR typically emerging during the first half of pregnancy and then decreasing. This phenomenon is influenced by raised levels of prolactin (PRL), human placental lactogen (hPL), progesterone, and estrogen, which contribute to the hyperplasia and hypertrophy of maternal pancreatic beta cells. These beta cell modifications are part of the body's physiological adaptation to hPL, a polypeptide hormone secreted by the placenta that peaks around 30 weeks of gestation [15]. This timing may explain why blood glucose levels tend to stabilize after 30-32 weeks of pregnancy. hPL decreases activation of insulin receptor substrate 1 (IRS1) through phosphorylation, thereby inducing IR [16]. PRL, another polypeptide hormone produced by the anterior pituitary gland, also affects insulin sensitivity and lipid metabolism. PRL can induce IR both during and outside the pregnancy period, working alongside hPL to contribute to IR [17]. Prolactin receptors, which are expressed in pancreatic beta cells, play a fundamental role in pregnancy metabolism as well as IR. These receptors regulate pro-proliferative and anti-apoptotic pathways through the mitogen-activated protein kinase (MAPK), protein kinase B (AKT), phosphatidylinositol 3-kinase (PI3K), the Janus kinase 2-signal transducer and activator of transcription 5 (JAK2/STAT5) pathway. After childbirth, beta-cell mass is reduced through apoptosis, cell size reduction, or other mechanisms [18]. Estradiol induces IR by activating the JNK pathway through membrane estrogen receptor (ER)-mediated actions and serine phosphorylation of IRS-1. Progesterone contributes to IR by inhibiting the PI3-kinase pathway and reducing IRS1 expression [19]. Placental growth hormone (PGH) is found in the syncytiotrophoblast and extravillous cytotrophoblast layers of the human placenta [20]. It promotes gluconeogenesis, lipolysis, and anabolism in maternal tissues. PGH plays an important role in maternal adaptation to pregnancy, ensuring adequate fetal growth and development by inducing physiological IR [21,22]. An overproduction of PGH has been observed in GDM, but this phenomenon is not fully understood and deserves further studies [18].

Recent research has emphasized the impact of inflammatory markers in the development of GDM. One mechanism that could induce physiological IR in pregnancy is the reduction in adiponectin synthesis, a protein hormone with more properties such as insulin-sensitizing and anti-inflammatory. Adiponectin inhibits the insulin intracellular signaling pathway, contributing to IR [18]. In contrast, leptin produced by adipocytes, the ovaries, and the placenta inhibits insulin action [23]. GDM is characterized by elevated oxidative stress exceeding levels that are typically seen in normal pregnancies along with an inflammatory state. Elevated oxidative stress leads to increased production of inflammatory cytokines and stimulates the appearance of free radicals. In GDM, reactive oxygen species (ROS) levels are elevated while total antioxidant capacity (TAC) is reduced. Pancreatic beta cells are particularly sensitive to ROS, and oxidative stress can induce beta cell dysfunction through apoptotic events. Additionally, oxidative stress reduces cellular glucose uptake and contributes to IR [24]. The pro-inflammatory environment in GDM may be explained by an increase in platelet-based growth factor and the subsequent formation of other pro-inflammatory cytokines (TNF-α, IL-1β, and IL-6) and chemokines (CXCL1, CXCL5, CXCL8, CCL2). During pregnancy, there is an elevated secretion of pro-inflammatory cytokines, which reduce insulin release from beta cells, impair insulin signaling, and contribute to IR [25,26].

It is crucial to detect hyperglycemia early in pregnancy because it can have harmful impacts on both the mother and the fetus, over both short and long periods**.**

Risk factors of GDM

Multiple factors contribute to the occurrence of GDM, including financial status, diet, lifestyle, physical activity, and history of diabetes in pregnant women's family or personal history of GDM [27]. The advanced age of the mother represents a significant risk factor. Women over 45 years old have a higher risk for hyperglycemia during pregnancy and associated complications [28]. It appears that women with a history of GDM may develop T2D within 5 to 10 years after childbirth, though not every woman with a history of GDM will progress to diabetes mellitus [2,29]. Excess weight and obesity, are also major contributing factors for GDM. Pregnant women with a higher body mass index (BMI≥ 29 kg/m²) are at heightened chance of developing GDM and experiencing pregnancy-related complications [30]. Excessive body weight has an important role in the deterioration of pancreatic beta cells. After a diagnosis of GDM, the most effective strategy for preventing T2DM is through lifestyle modifications or medications that improve biological outcomes and reduce IR [31]. Diet is another important factor: intake of fat-rich foods, sugary products, as well as red meat increases the likelihood of GDM, while a fiber-rich diet, micronutrients, and polyunsaturated fatty acids can reduce the risk. Additionally, a history of PCOS and multiparity significantly increases the likelihood of GDM and related metabolic complications [32]. Having a family history of diabetes or GDM during a previous pregnancy also raises the chance of developing GDM [2].

Pregnant women with at least one risk factor for diabetes should be early tested (<20 weeks) to establish or not the diagnosis of early GD. Once the diagnosis is established, the treatment must be initiated quickly [33].

Screening and diagnosis of GDM

Over time, the methods for diagnosing GDM have evolved from targeted screening solely on risk factors to the utilization of the oral glucose tolerance test (OGTT) for universal screening [34]. Advanced maternal age (over 30 years) is a major risk factor associated with GDM [28]. Women who have previously given birth to a baby weighing over 4 kilograms or had GDM in a prior pregnancy or are overweight or with a family medical previous occurrence of T2D are considered at higher likelihood for developing GDM. Additionally, women with polycystic ovary syndrome (PCOS) and those with pluriparity are at greater risk [35].

Glycemic targets during pregnancy are more stringent than those for nonpregnant women. According to ADA the screening for GDM is recommended between 24 and 28 weeks of gestational period among pregnant women who have not been before diagnosed with diabetes. Pregnant women with diabetes must consume consistent carbohydrates to establish their insulin doses and avoid both low and high glucose levels, as these conditions can adversely affect the fetus [36]. In 2010, the Hyperglycemia and Adverse Pregnancy Outcome (HAPO) study introduced other targets for OGTT, prompting a reassessment of the diagnostic criteria for GDM identified between 24 and 28 weeks of pregnancy. These thresholds have been endorsed by the WHO and Croatian Society for Gynecology-Obstetrics [37].

1. The One-Step Strategy (derived from the IADPSG criteria) involves a 75-gram OGTT. It is performed in the morning, after at least 8 hours of fasting. Blood glucose levels are evaluated at fasting, 1 hour, and 2 hours in individuals who have not been formally diagnosed with diabetes (Table 1). A positive assessment is established if glucose levels are achieved or excelled [36].

Table 1: The One-Step Strategy (adapted from [36])

Fasting	≥ 92 mg/dL (5.1 mmol/L)
1 hour	≥ 180 mg/dL (10.0 mmol/L)
2 hours	≥ 153 mg/dL (8.5 mmol/L)

2. The Two-Step Strategy involves an initial 50-gram OGTT (non-fasting) and followed by a 100-gram OGTT if the first test is positive according to Carpenter-Coustan criteria. The American College of Obstetricians and Gynecologists (ACOG) and the National Institutes of Health (NIH) recommend this strategy for diagnosing GDM [36].

Step 1: A 50-gram OGTT (non-fasting) is administered, and glucose level is measured an hour later. If the plasma glucose value is ≥ 130 mg/dL (7.2 mmol/L), 135mg/dL (7.5 mmol/L), or 140 mg/dL (7.8 mmol/L), the patient proceeds to Step 2.

Step 2: A 100-gram OGTT (fasting) is performed, with glucose levels assessed at fasting, 1 hour, 2 hours, and 3 hours. If two or more of the following glucose thresholds are reached, GDM is confirmed (Table 2).

Table 2: The Two-Step Strategy (adapted from [36])

Fasting	≥ 95 mg/dL (5.3 mmol/L)
1 hour	≥ 180 mg/dL (10.0 mmol/L)
2 hours	≥ 155 mg/dL (8.6 mmol/L)
3 hours	≥ 140 mg/dL (7.8 mmol/L)

The assessment of GDM is based on these standards adapted from [36], [38], [39].

Postpartum evaluation for women experienced GDM is recommended from 4 to 12 weeks after childbirth. This screening should use a 75-gram OGTT, and the diagnosis should be based on non-pregnancy criteria [36].

Complications while pregnant: for mother as well as newborn

Effects on the mother

Short-term complications. GDM can lead to several short-term complications during pregnancy. These include high blood pressure (hypertension), pre-eclampsia, spontaneous abortion, the need for a cesarean section, and difficulties during childbirth [9]. If the fetus is macrosomic, vaginal delivery becomes riskier. Instrumental delivery, using forceps or a vacuum, may be necessary, or an unexpected or emergency cesarean section might be required. Large babies increase the likelihood of perineal tears, vaginal lacerations, and other birth injuries [40]. Additionally, macrosomic births carry risks such as uterine atony, heavy bleeding, postpartum hemorrhage, and genital tract injuries. These risks are further heightened if the mother has previously had a cesarean section [13].

Long-term complications. In chronic complications, mothers experiencing GDM have high risk of recurrence in future pregnancies and a greater likelihood of onset of T2D in the future [2]. The HAPO (Hyperglycemia and Adverse Pregnancy Outcomes) research found that maternal elevated blood sugar during pregnancy was associated with a higher risk of early childbirth, cesarean delivery, macrosomia, congenital malformations, neonatal intensive care unit admission, hyperbilirubinemia, and neonatal hypoglycemia [41]. Generally, GDM resolves after childbirth.

Effects on the newborn

Fetal complications such as premature birth, hypoglycemia at birth, shoulder dystocia, Erb's palsy, congenital anomalies, and fetal macrosomia are common in pregnancy with GDM. Neonatal respiratory distress syndrome and low Apgar scores are also potential issues. This respiratory distress can be linked to alterations in the integrity and composition of fetal pulmonary surfactant, as GDM can delay the secretion of essential surfactant components, such as phosphatidylglycerol [42]. Infants born to mothers with GDM have a higher likelihood of evolving overweight and T2D later in life [14].

Fetal macrosomia is the most common difficulty associated with GDM. It is characterized by a birth weight of 4 kilograms or more. This condition is marked by an increase in the abdominal diameter and scapular area of the fetus [43]. Excess glucose, which crosses the placenta, serves as the primary energy substrate for fetal growth. Elevated maternal glucose levels lead to increased glycogen storage in the fetus, resulting in fetal hyperinsulinemia and an increase in adipose tissue [44,45]. Macrosomic newborns often exhibit asymmetrical growth, characterized by central deposition of subcutaneous fat around the abdomen and back, increased shoulder circumference, and more skin folds [46].

Treatment of late GD brings benefits to both the mother and unborn baby, but more recent studies highlight that the treatment started even earlier (in early GD) brings even more benefits, both in the long term and in the short term [47]. The Treatment of Booking Gestational Diabetes Mellitus (TOBOGM) clinical trial was the first study to evaluate the effectiveness of immediate initiation of treatment in patients diagnosed with early GD in terms of pregnancy complications. There was a significant reduction in the risk of neonatal adverse events in the group in which the treatment was initiated immediately [33].

Treatment (blood glucose monitoring, lifestyle changes, pharmacotherapy)

The main goal of treating GDM is to reach and sustain the optimal blood glucose range. Mothers must understand the condition and aim to manage their blood sugar levels effectively [9,13].

Blood glucose monitoring in pregnancy

In managing GDM daily monitoring of blood sugar at home is very important. Expectant mothers with diabetes should regularly check their glucose levels, including fasting and postprandial (after meal) readings. For those using basal-bolus therapy or insulin pumps, preprandial (before meal) testing is also recommended. ADA sets target values for blood sugar levels as follows: fasting - must be below 95 mg/dL (<5.3 mmol/L), 1-hour postprandial glucose should be below 140 mg/dL (<7.8 mmol/L), and 2 hours postprandial glucose should be below 120 mg/dL (<6.7 mmol/L). For managing hypoglycemia, thresholds are set at less than 70 mg/dL (<3.9 mmol/L) for blood sugar and less than 63 mg/dL (<3.5 mmol/L) for sensor glucose. Glycated hemoglobin (A1C) is used as an additional measure of glycemic control rather than for diagnosing GDM, as A1C levels can be influenced by changes in red blood cell exchange during pregnancy. Consequently, A1C may need to be monitored more frequently, such as monthly [9]. Factors like increased vitamin C intake accelerated red blood cell renewal, and higher iron demands during pregnancy can lower A1C levels [48,49]. Continuous glucose monitoring (CGM) is another valuable tool, providing real-time tracking of glucose levels throughout the day and night. This method helps in monitoring glucose fluctuations and offers data that can improve both patient and clinician management of GDM, enhancing patient compliance and reducing the discomfort associated with frequent finger pricks

[49].

Lifestyle changes

The first step in managing GDM involves lifestyle modifications, including nutritional support therapy, regular active lifestyle, and body mass control based on weight before pregnancy [9,13]. For many pregnant women, these changes may be sufficient to control GDM.

Nutrition. The dietary plan should ensure sufficient calorie intake to aid both the mother and the unborn baby, although the ideal calorie amount during pregnancy for women with GDM has not been established. The nutrition plan should be aligned with the recommendations of the National Academy of Medicine. It is suggested that the dietary reference intake for all expecting women includes a starting amount of 175 grams of carbohydrates (thirty-five percent of 2,000 calories per day), at least 71 grams of protein, and 28 grams of fiber [9, 50]. Emphasizing superior quality, carbohydrates rich in nutrients help to maintain regulated pre-meal and post-meal glucose levels, whereas simple carbohydrates can lead to higher post-meal glucose excursions [9]. A diet rich in whole foods, such as fresh produce, veggies, fruits, beans, whole cereals, and healthy fats (including omega-3 fatty acids from nut products, seeds, as well as fish) is highly recommended. Processed foods, sweetened foods, beverages, and consumption of fatty red meats should be reduced. An expert panel on nutrition advises a balanced intake of primary nutrients and cautions against very restrictive diets, trans fats, ketogenic diets lacking carbohydrates, dairy-restricted diets, and those high in saturated fats [9,51].

Physical activity can improve blood glucose control and decrease the need for insulin. Recommended exercises include aerobic activities, resistance training, or a combination of both. The duration should last between 20 to 50 minutes daily, 2 to 7 days a week, at medium force [9,52].

Pharmacotherapy

The next step in managing GDM involves the use of medication. Up to 30 percent of women with GDM will require pharmacotherapy [53]. Insulin is the preferred pharmacological treatment for GDM when lifestyle modifications (diet and exercise) fail to achieve blood glucose targets. Due to its large molecular size, insulin does not cross the placenta, being safe for the fetus [9,54]. The insulin doses must be calculated according to glycemic values and the amount of carbohydrates consumed. Long-acting insulin (detemir or glargine) may be used for basal glucose control. Rapid (lispro or aspart) or short (regular) insulin is used to control elevated post-prandial blood sugars [55,56,57]. In addition, short-acting insulin analogs have a lower risk of hypoglycemia and offer greater flexibility in administration compared to human insulin [58]. For pregnant women with both higher fasting and postprandial blood sugar basal-bolus is used: 50% of the total daily dose of long-acting insulin and 50% of the total daily dose of short or rapid-acting insulin. In the first trimester of pregnancy, insulin is initiated with 0.7 U/Kg/day and can reach up to 1U/kg/day until birth. In some cases of pregnancy, intermediate-acting insulin (neutral protamine Hagedorn (NPH)) can also be used: 2/3 of total daily insulin before breakfast and 1/3 of TDD before dinner [55,56, 57]. Recently ultra rapid-acting insulin aspart (Fiasp) and lispro (Lyumjev) have received approval for use in pregnancy [58]. Emerging yet limited evidence suggests that insulin degludec may be suitable for use in pregnancy [59]. Also, the data regarding the effectiveness and risks of glulisine and glargine U-300 insulin administration during pregnancy is still limited [4]. Insulin pumps are not yet recommended for women with GDM because the clinical data is still limited [58].

Oral medications that have been researched include metformin and glyburide. These oral antidiabetic drugs do pass through the placental membrane and should not be used as first-line treatments. Sulfonylureas, such as glyburide, have been linked with elevated risks of neonatal hypoglycemia, macrosomia, and a larger abdominal circumference [9,54]. Fetuses exposed to metformin have shown smaller head and chest circumferences, reduced birth size, and decreased lean mass [60]. These oral antidiabetic drugs can impact fetal development and growth.

CONCLUSIONS

GDM is an increasingly common complication with negative outcomes for both the mother and the unborn child. It is described by the body's lack to compensate for the physiological IR that occurs during pregnancy. Although many factors of risk contribute to the development of GDM. IR looks to be the primary factor which in turn triggers other mechanisms. The placenta also plays an important role in the onset of GDM. Inflammatory markers, along with placental hormones, are involved in this process which is not yet fully understood. These changes impact fetal development and growth, making early diagnosis and prompt treatment of GDM crucial to reducing the risk of complications.

Additionally, early postnatal preventive approaches should be considered in reducing the development from GDM to T2D, thereby increasing awareness of this condition during pregnancy. However, there are still many steps to be taken towards establishing an international prevention strategy and accurately determining the mechanisms involved in the development of GDM.

Conflicts of interest and sources of funding

The authors declare no conflict of interest, and this research has received no external funding.

Ethics approval and consent to participate

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at office@rjmm.ro.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers may cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor may not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Academic Editor. The Editor-in-Chief reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at: http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

– Accessible to the public at no charge;

– Searchable by standard, electronic (Internet-based) methods;

– Open to all prospective registrants free of charge or at minimal cost;

– Validates registered information;

– Identifies trials with a unique number; and

– Includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, a target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal, you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The Journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 200 words. Abstracts for original articles should be formatted as detailed in the word form. Titles must not be longer than 120 characters (including spaces). In every article, there must be three to ten pertinent keywords specific to the article yet reasonably common within the subject discipline.

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article. This should be cited as Rom. J. Mil. Med. (year); (vol): [issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related “miniseries” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this

avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-analyses and Systematic Reviews are suggested to be limited to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are suggested to be limited to 3000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Executive Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In Part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate.

Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication, as presented at http://www.ICMJE.org/.

Spelling

The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units

All measurements must be given in SI units as outlined in the latest edition of Units, Symbols, and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations

Abbreviations should be used sparingly and only where they ease the reader's task by reducing the repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: the title page; and the main text file according to the word model.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or an article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented according to the word model. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 200 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. If appropriate, divide the abstract with the headings: Background and Aim, Methods, Results, and Conclusions. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to ten keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser – http://www.nlm.nih.gov/mesh/meshhhome.html.

Text

Authors should use the word form in editing the submitted material.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square parentheses in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or fewer; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

Use Index Medicus as the style guide for references and other journal abbreviations.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table and legend must be

understandable without reference to the text. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, •, ‣ should be used (in that order) and *, **, *** should be reserved for P-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication:

Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at office@rjmm.ro. A cover letter containing an authorship statement should be included. The cover letter should include a statement covering each of the following areas:

– Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author. It is not accepted the idea of equal contribution.

– Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.

– A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

– For research involving pharmacological agents, devices, or medical technology, a clear Conflict of Interest statement about any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

– For clinical trials, these have been registered in a publicly accessible database (see more under 'ETHICAL CONSIDERATIONS (Further Information)' later in these guidelines).

If the above items are not included in the cover letter, manuscripts cannot be sent for review. Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using the word model that is to be found on the web page (http://revistamedicinamilitara.ro/wpcontent/uploads/2022/07/Macheta-articole.docx).

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, high-resolution figures (at least 300 d.p.i.) saved as .eps, .jpg or .tif files are required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted Articles

Accepted Articles are published online after final acceptance, and appear in PDF format only.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing the proof of acceptance. It is therefore essential that a working e-mail address is provided for the corresponding author.

COPYRIGHT, LICENSING, AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is submitted.

Abstract: *Post-traumatic stress disorder (PTSD) is a condition associated with high levels of stress often linked to elevated resting blood pressure (BP). Beta-hydroxybutyrate, a fuel source and signaling molecule, has been shown to improve metabolic and neurological conditions, as well as decrease systolic BP in healthy populations. The purpose of this study was to determine if long-term beta-hydroxybutyrate administration via ketone salt (KS) supplementation alters BP, complete blood count (CBC), or comprehensive metabolic panel (CMP) results in adults diagnosed with PTSD. Sixteen adults (ages 21-65; 12 women/4 men) with PTSD completed this randomized, double-blinded, and placebo-controlled study by taking KS or a placebo supplement for 6 weeks. Blood was collected (for CMP and CBC assessment) and BP measurements were taken before and after the intervention period. None of the variables changed significantly based on the condition (p > .05 for all interaction effects). The reduction in BP measures following the KS supplementation, though non-significant, may be clinically meaningful in PTSD populations and others subject to increased cardiovascular mortality risk. Chronic KS supplementation did not negatively impact BP, CBC, or CMP measures in adults with PTSD. Further investigation of KS as a hypertension treatment approach is warranted in this population.*

Keywords: *PTSD, ketone salts, blood pressure, cardiovascular, comprehensive metabolic panel, complete blood count, beta-hydroxybutyrate, hypertension*

INTRODUCTION

Post-traumatic stress disorder (PTSD) is a highly prevalent and impairing mental condition brought on by the occurrence of a traumatic life event(s) [1,2]. According to the U.S. Department of Veterans Affairs, an estimated 6 in 100 people will suffer from PTSD at some point during their lifetime; in 2020 approximately 13 million American adults were estimated to have PTSD [3]. Only a minority of those with PTSD obtain treatment [1]. Individuals who suffer from this may experience flashbacks and invasive thoughts concerning the event, as well as nightmares, emotional numbness, and loss of interest in daily activities [4-6]. In addition to psychological ramifications, PTSD symptoms manifest in the physical health of these individuals [7].

Hyperarousal is characteristic of PTSD which may result in elevated resting blood pressure and/or heart rate commonly found in this population [8,9]. Previous findings, though controversial, demonstrate an association between PTSD and elevated levels of proinflammatory blood markers [10]. Compared to the general population, those diagnosed with PTSD are at a higher risk of developing cardiovascular disease, autoimmune disorders, metabolic syndrome, obesity, diabetes, and atherosclerosis [11-14]. Negative health behaviors previously associated with PTSD, such as smoking, increased weight, and physical inactivity, may attribute to these increased risks [15,16]. Since a minority seeks professional treatment options, holistic, at-home remedies need to be identified and examined for efficacy.

Elevating circulating ketone bodies, specifically beta-hydroxybutyrate, has been shown to significantly improve a range of metabolic and neurological disorders [17-19]. For example, beta-hydroxybutyrate has been shown to inhibit the NLRP3 inflammasome, a multiprotein complex that induces neuroinflammation in the hippocampus, with antidepressant and anti-inflammatory effects on rats exposed to acute and chronic stress [20]. Through several mechanistic effects, increased circulating beta-hydroxybutyrate may positively affect psychiatric disorders by enhancing brain energy metabolism, promoting repolarization of the neuronal membrane, decreasing hyperexcitability and neuronal firing, modulating neurotransmitter release and balance, decreasing inflammatory processes, and providing neuroprotective effects [21-26]. Strategies to increase circulating beta-hydroxybutyrate levels include maintaining a low-carbohydrate, high-fat ketogenic diet, and/or supplementing with exogenous ketones; both approaches demonstrate therapeutic benefits [22,27,28]. Rigorous adherence to a ketogenic diet is required to increase ketone levels in the blood but is difficult to achieve, especially in the psychiatric population [19]. Exogenous ketone supplements increase circulating ketone levels and require no dietary changes other than consuming the ketones, usually in drink form [27,29]. Similar to dietary-induced endogenous ketones, exogenous ketone supplements provide a fuel source and evoke signaling-based physiological modifications [30,31]. Therefore, elevating circulating ketone levels via long-term administration of exogenous ketone supplements may allow for a more accurate examination of the effects of ketones in the PTSD-diagnosed population.

Previously, we have demonstrated that supplementing with ketone salts for 6 weeks seems safe in terms of blood health parameters and blood pressure in a healthy population, even showing a significantly reduced systolic blood pressure [29]. Prior to examining the therapeutic effects of ketone salts, it is important to determine if they alter basic health variables and seem safe. Studies demonstrating the effects of increased circulating ketone levels on psychiatric disorders in humans are limited and need to be explored due to their therapeutic properties [21]. Therefore, the aim of this 6-week pilot study was to determine if daily consumption of exogenous ketone salts alters blood pressure and/or blood health parameters in individuals diagnosed with PTSD.

MATERIALS AND METHODS

Experimental Design

This randomized, double-blinded, placebo-controlled, six-week clinical trial consented individuals previously diagnosed with PTSD. Participants were randomized to either a placebo (PLA) or ketone salt (KS) group. Both the PLA and KS groups were asked to maintain a normal diet, consume their provided supplement twice daily, and maintain their normal medication schedule throughout the 6-week period. The PLA and KS supplements were sent to the experimental laboratory by the manufacturer in white packages coded “A” or “B”, and participant numbers 1-24 were randomly assigned to supplement ‘A’ or ‘B’ prior to recruiting or consenting participants. The study was approved by Augusta University’s Institutional Review Board, and all procedures were in compliance with the institutional guidelines. All participants signed an informed consent with a study-approved investigator prior to participating. The study is registered with ClinicalTrials.gov with the ID# NCT04083352.

Participants

Inclusion criteria to participate in this study were: 1) a previous diagnosis of PTSD and 2) men and non-pregnant women between 18-65 years old. Participants were recruited through email solicitation via the University’s Veteran Success Department, the Augusta Warrior Project, as well as through the local news station. Twenty-one participants consented to the study and 14 completed it, including 3 males and 11 females. Participant demographics are provided in Table 1.

Table 1: Participant demographics and p-value of t-test comparing baseline characteristics between groups (ketone salts, KS; placebo, PLA)

Measure	KS (*n*=7; 5 women)	PLA (*n*=7; 6 women)	*p*
Age (years)	42.85 (9.01)	49.14 (11.05)	.266
Height (cm)	171.78 (9.31)	166.71 (8.57)	.310
Weight (kg)	93.37 (23.08)	86.16 (18.26)	.529
BMI (kg/m^2)	31.21 (4.76)	31.07 (6.61)	.964

Procedures

Participants visited the laboratory twice for data collection, once at the beginning of the study for baseline data and again 6 weeks later after supplementing with their assigned supplement.

Prior to the two laboratory visits, participants were asked to fast and refrain from exercise for at least 8 hours, refrain from caffeine and nicotine for at least 12 hours, and refrain from consuming alcohol for at least 24 hours. During the two laboratory visits, participants filled out a health history questionnaire, took a pregnancy test if female, had height, weight, resting heart rate, and blood pressure measured, and then had a venous blood draw to use for comprehensive metabolic panel (CMP) and complete blood count (CBC) analyses.

Measures

Height was measured using a stadiometer (Stadi-o-meter; Novel Products, Inc., Rockton, IL, USA), and weight was measured using a beam balance scale (Healthometer; Continental Scale Corporation, Bridgeview, IL). Resting blood pressure and heart rate were recorded 5 minutes after resting with an automated blood pressure cuff (10 Series Upper Arm Blood Pressure Monitor; Omron Healthcare, Inc, Kyoto, Japan).

Venous blood samples were collected into an ethylenediaminetetraacetic acid (EDTA) anticoagulant-sealed vacutainer and two lithium heparin-sealed vacutainers. The samples were then transported directly to the Clinical Pathology Lab at Augusta University Hospital for analysis of CMP and CBC. The CMP included analysis of plasma sodium, potassium chloride, carbon dioxide, blood urea nitrogen (BUN), creatinine, calcium, glucose, total protein, albumin, total bilirubin, alkaline phosphatase, aspartate amino-transferase (AST) and alanine transaminase (ALT) levels. The CMP was performed on an automated chemistry analyzer (ADVIA 1800 Chemistry System; Siemens Healthineers, Erlangen, Germany). The CBC included analysis of whole blood levels of white blood cells (WBC), red blood cells (RBC), hemoglobin (Hgb), hematocrit (Hct), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), mean corpuscular volume (MCV), red cell distribution width percent (RDW), platelets (PLT) and mean platelet volume (MPV). The CBC was analyzed with a cellular analysis system (UniCel DxH 800 Hematology Analyzer Workstation; Beckman Coulter, Brea, CA).

Supplement

Participants were randomized to consume two servings per day of either KS or PLA supplements for 6 weeks (84 total servings) after the first data collection visit. Participants were encouraged to consume one serving in the morning and one in the late afternoon while maintaining their typical diet. Participants were asked to fill out daily supplement logs to confirm adherence to consuming the assigned supplement.

The KS and PLA supplements were flavor- and calorie-matched (fruit punch and 41 calories, respectively), and were provided in a powder form that was to be mixed with water. The KS supplement consisted of 7 grams of beta-hydroxybutyrate combined with erythritol, L-Taurine, fermented L-Leucine, citric acid, natural flavor, vegetable juice color, stevia, xanthan gum, beta carotene and approximately 920 mg of sodium (KETO//OS® MAX, Pruvit Ventures, Inc., Melissa, TX). The PLA supplement included similar color, sodium, and flavoring as the KS supplement but with maltodextrin in place of the beta-hydroxybutyrate.

Statistical Analysis

All analyses were performed with SPSS version 29 by a statistician who was blinded from any information pertaining to the group assignment of all participants. A predetermined alpha level of .05 was used in all cases unless otherwise specified. Any missing data was excluded from analysis via pairwise deletion, leading to slightly different sample sizes for some analyses. Demographic variables (age, height, weight, and BMI) at baseline were compared between the KS and PLA groups using paired-sample t-tests to verify similar participant characteristics in each group. Body weight was compared before and after the intervention period in each group using paired samples t-tests to assess weight change during the intervention period.

A series of 2 (group: control or ketones) x 2 (time: PRE and POST) mixed factorial ANOVAs was performed to assess the changes in each dependent variable in each group over time for BP, CMP, and CBC measures. Data were screened for outliers (> 3.0 SD units from the mean) prior to analysis. The assumptions of homogeneity of variance and covariance were assessed with Levene's test and Box's test, respectively. Violations of these assumptions are reported with relevant results. In the case of a significant interaction effect, Bonferroni-adjusted post hoc tests were performed. Effect size is reported as partial eta squared (η^2) and is interpreted according to the guidelines described by Cohen (2013) as small (η^2=0.01), medium (η^2=0.06), and large (η^2=0.14) [32].

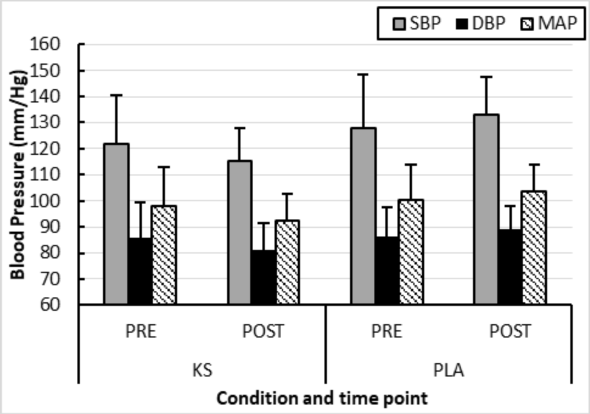
RESULTS

Cardiovascular and body weight measures

There was no interaction effect, or main effects of condition or time, respectively, for SBP (p=.120 and η^2=.175; p=.154 and η^2=.150; p=.849 and η^2=.003), DBP (p=.174 and η^2=.137; p=.442 and η^2=.046; p=.701 and η^2=.012), or MAP (p=.124 and η^2=.172; p=.266 and η^2=.094; p=.743 and η^2=.009). Results for SBP, DBP, and MAP are presented graphically in Figure 1.

Similarly, there were no significant effects for RHR (p=.349 and η^2=.080; p=.832 and η^2=.004; p=.286 and η^2=.103) which increased from PRE to POST in the KS condition (73.86±15.61 bpm vs. 81.14±15.91 bpm) and the PLA condition (75.67±13.26 bpm vs. 76.17±12.58 bpm). Among participants with complete data, there was no significant change in body weight from PRE to POST for KS (103.32±23.82 kg vs. 103.3±25.23 kg; p=.973) or PLA (87.1±17.11 kg vs. 87.95±17.12 kg).

Figure 1: Cardiovascular measures before (PRE) and after (POST) 6-week intervention period (ketone salts, KS; or placebo, PLA). SBP (systolic blood pressure), DBP (diastolic blood pressure), and MAP (mean arterial pressure) values are presented. Bars represent mean values and whiskers represent standard deviations



Comprehensive metabolic panel

ALT did not meet the assumption of homogeneity of variance for either time point. No interaction effect or main effect of time was observed for ALT (p=.870 and η^2=.006; p=.941 and η^2=.001, respectively). However, there was a main effect of condition for ALT (p=.009 and η^2=.775). ALT was higher in KS (39.13±7.08 U/L) than in PLA (16.67±7.08 U/L).

There was no interaction effect, or main effects of condition or time, respectively, for ketones (p=.349 and η^2=.080; p=.832 and η^2=.004; p=.286 and η^2=.103), sodium (p=.918 and η^2=.002; p=.160 and η^2=.300; p=.798 and η^2=.012), potassium (p=.551 and η^2=.062; p=.350 and η^2=.146; p=.480 and η^2=.086), chloride (p=.941 and η^2=.001; p=1.00 and η^2=.000; p=.768 and η^2=.016), CO2 (p=.852 and η^2=.006; p=.287 and η^2=.185; p=.666 and η^2=.033), BUN (p=.114 and η^2=.363; p=.762 and η^2=.017; p=.197 and η^2=.260), creatinine (p=.902 and η^2=.003 ; p=.670 and η^2=.032; p=.206 and η^2=.251), glucose (p=.691 and η^2=.028; p=.554 and η^2=.061; p=.898 and η^2=.003), calcium (p=.117 and η^2=.358; p=.897 and η^2=.003; p=.291 and η^2=.183), protein (p=.690 and η^2=.028; p=.707 and η^2=.025; p=.909 and η^2=.002), albumin (p=.212 and η^2=.245; p=.906 and η^2=.003; p=.828 and η^2=.009), AST (p=.706 and η^2=.025; p=.075 and η^2=.435; p=.510 and η^2=.076); alkaline phosphate (p=.770 and η^2=.015; p=.388 and η^2=.126; p=.363 and η^2=.139), or bilirubin (p=.775 and η^2=.015; p=.463 and η^2=.093; p=.496 and η^2=.081). Descriptive statistics for all comprehensive metabolic panel variables are presented in Table 2.

Complete blood count

No interaction effect or main effect of time was observed for MCV (p=.520 and η2=.061; p=.203 and η2=.220, respectively). However, a main effect of the condition for MCV (p=.018 and η2=.573). MCV was higher in KS (90.72±2.84) than PLA (84.55±2.84).

There was no interaction effect, or main effects of condition or time, respectively, for WBC (p=.565 and η^2=.050; p=.227 and η^2=.200; p=.664 and η^2=.028), RBC (p=.597 and η^2=.042; p=.597 and η^2=.042; p=.943 and η^2=.001), Hgb (p=.527 and η^2=.060; p=.393 and η^2=.106; p=.831 and η^2=.007), Hct (p=.749 and η^2=.016; p=.434 and η^2=.089; p=.831 and η^2=.007), MCH (p=.649 and η^2=.031; p=.129 and η^2=.297; p=.304 and η^2=.149), MCHC (p=.456 and η^2=.082; p=.904 and η^2=.002; p=.823 and η^2=.008), RDW (p=.727 and η^2=.019; p=.129 and η^2=.298; p=.312 and η^2=.145), PLT (p=.333 and η^2=.134; p=.228 and η^2=.200; p=.786 and η^2=.011), or MPV, which did not meet the assumption of homogeneity of covariance (p=.815 and η^2=.008; p=.299 and η^2=.152; p=.132 and η^2=.293). Descriptive statistics for all complete blood count variables are presented in Table 3.

DISCUSSION

The findings from this pilot study demonstrate that chronic ketone salt supplementation is safe for individuals diagnosed with PTSD. After supplementing with ketone salts twice daily for 6 weeks, blood pressure and blood health parameters including CMP and CBC remained unaltered. There was a trend toward a reduction in blood pressure after consuming ketone salts and may have clinical significance as it changed the average from hypertensive to normal levels.

Individuals diagnosed with PTSD suffer from health issues including, but not limited to, high blood pressure, depression, and anxiety with increased risk for cardiovascular disease, diabetes, and autoimmune disease [11-13]. Because of the compounding negative health effects related to PTSD, and the large population of individuals affected by this condition, it is important to find therapeutic approaches that may reduce PTSD symptoms and risk factors [1,2]. Ketone salt supplementation has been shown to improve many of these health issues in animal and/or human models [17,18].

Table 2: Descriptive statistics for the comprehensive metabolic panel before (PRE) and after (POST) 6-week intervention period (ketone salts, KS; placebo, PLA). Mean values are reported with standard deviations in parentheses, i.e. "M (SD)". Measure units are specified next to each variable name

Measure	KS		PLA	
	PRE	POST	PRE	POST
Ketones (mg/dL)	0.13 (0.10)	0.13 (0.08)	0.17 (0.12)	0.10 (0.06)
Sodium (mEq/L)	136.40 (1.52)	137.80 (1.30)	136.67 (1.53)	137.67 (0.58)

ALT (U/L)	39.25 (12.99)	39.00 (5.48)	16.33 (2.52)	17.00 (2.65)
Alkaline Phosphate (U/L)	71.40 (19.76)	75.20 (25.99)	58.33 (13.43)	60.33 (17.79)
Bilirubin (mg/dL)	0.60 (0.24)	0.68 (0.31)	0.50 (0.10)	0.53 (0.15)

Table 3: Descriptive statistics for the comprehensive metabolic panel before (PRE) and after (POST) 6-week intervention period (ketone salts, KS; placebo, PLA). Mean values are reported with standard deviations in parentheses, i.e. "M (SD)". Measure units are specified next to each variable name

Measures	KS		PLA	
	PRE	POST	PRE	POST
WBC (x10^9L)	8.18 (2.40)	8.88 (3.31)	6.37 (1.52)	6.27 (1.14)
RBC (x10^{12}L)	4.68 (0.41)	4.72 (0.35)	4.88 (0.47)	4.82 (0.42)
Hgb (g/dL)	14.40 (1.10)	14.50 (1.23)	13.90 (0.36)	13.70 (0.95)
Hct (%)	42.58 (3.89)	42.68 (3.36)	41.10 (1.82)	40.60 (2.60)
MCV (fL)	91.05 (1.61)	90.38 (1.11)	84.67 (4.58)	84.43 (5.00)
MCH (pg)	30.77 (0.99)	30.70 (0.89)	28.70 (2.90)	28.53 (2.91)
MCHC (g/dL)	33.80 (1.37)	33.98 (0.91)	33.83 (1.50)	33.73 (1.43)
RDW (%)	13.45 (0.74)	13.25 (0.45)	14.00 (0.10)	13.90 (0.30)
PLT (x10^9L)	247.17 (59.17)	267.50 (41.19)	300.67 (14.01)	289.00 (34.83)
MPV (fL)	9.05 (0.96)	8.80 (0.86)	8.17 (1.89)	7.83 (1.47)

Ketones are a preferred fuel source, especially for the brain as they can cross the blood-brain barrier to enter the brain cells and ultimately provide energy for the central nervous system [32]. Animal studies have demonstrated therapeutic benefits for similar psychiatric symptoms including anti-anxiety and antidepressant effects possibly due to a reduction in neuroinflammation [20,22].

We previously demonstrated that chronic ketone salt supplementation reduced systolic blood pressure in a healthy population; the PTSD study described herein demonstrated a trend toward reduced blood pressure. Kimura et al. (2011) demonstrated that beta-hydroxybutyrate inhibits sympathetic activity by interacting with G protein-coupled receptor 41, a receptor involved in the regulation of the sympathetic nervous system [34]. The inhibition of the sympathetic nervous system from beta-hydroxybutyrate is a possible explanation for reduced blood pressure after chronic consumption of ketone salts [35]. A common concern of ketone salt supplements is the potential negative health effects that may result from the high sodium content of the supplement. One serving of the ketone salt supplement used in this study contained 914 mg of sodium which is almost 40% of the daily recommended sodium content. However, our study in healthy individuals as well as in this PTSD population found unaltered blood sodium levels and blood pressure were not negatively affected after consuming two servings of ketone salts for 6 weeks [29].

The effect of KS on BP measures over time, although not statistically significant, was substantial as noted by the large effect sizes reported and corresponding reductions in SBP, DBP, and MAP (6.5, 4.8, and 5.3 mmHg, respectively). Hypertension is typically defined as resting values of SBP>120 or DBP>80, though there is a clearly documented positive linear relationship between BP and mortality from cardiovascular causes at any level above 115/75 mmHg, wherein a higher BP is associated with increased risk [36,37]. To add perspective, Ettehad et al. (2016) estimated that for every 10 mmHg reduction in SBP, people with hypertension experience >20% reductions in CVD events, stroke, and heart failure, as a population [38]. If a reduction in blood pressure of any magnitude (at or above healthy levels) is considered clinically meaningful based on these findings from large-scale clinical trials, then supplementing one's diet with KS could be seen as an attractive alternative to traditional hypertension medications which may be contraindicated or have adverse effects [39]. It is also noteworthy that the reductions in SBP, DBP, and MAP observed here were in participants who were for the most part very close to healthy BP levels. If a similar intervention was completed in participants with hypertension, a more substantial, and possibly significant, antihypertensive effect may result.

Studies examining the efficacy of exogenous ketone supplementation on PTSD or other psychiatric disorders in humans are limited, and therefore this needs further investigation. Future studies exploring the effects of exogenous ketone supplementation on cardiovascular parameters in people with PTSD should include a group without PTSD for comparison and larger sample size, as these were two primary limitations of this study.

CONCLUSION

Chronic ketone salt supplementation did not alter CMP or CBC, blood health parameters indicative of liver and kidney function as well as infection and disease, in individuals diagnosed with PTSD. Blood pressure and heart rate were unaltered, although blood pressure trended toward a reduction from hypertensive to normal levels, which may be clinically meaningful in terms of cardiovascular mortality risk. This small pilot study suggests that ketone salt supplementation does not negatively impact cardiovascular or blood health parameters and should be further explored as a potential therapeutic approach for PTSD and related cardiovascular comorbidities.

Conflicts of interest and sources of funding

The authors declare no conflicts of interest. Angelia Holland-Winkler received funding for this project from Augusta University's College of Education and Human Development and Prüvit Ventures, Inc. Ketone and placebo supplements were provided by Prüvit Ventures, Inc.

Authors' contribution

Conceptualization, A.H-W; methodology, A.H-W; formal analysis, A.M.; investigation, A.H-W; writing—original draft preparation, J.L., A.M., A.H-W; writing—review and editing, J.L., A.M., A.H-W; supervision, A.H-W; funding acquisition, A.H-W. Abstract: *Spiritual care is an integrated section of nursing. Proper implementation of it to patients requires that care providers have the necessary competencies in this regard. Therefore, this study was performed to investigate the effect of an empowering program on spiritual care competence (SCC) in nursing students. This study was a randomized controlled trial that was performed on 60 nursing students at Kashan University of Medical Sciences, Iran. Participants were randomly assigned to two groups. The intervention group was under the spiritual empowering plan in seven sessions. The control group was traditionally trained. Data were collected by a spiritual care competence scale and analyzed using Fisher, independent and paired t-test in SPSS 16v. Baseline characteristics were similar in the two groups. The mean score of SCC was significantly increased post-empowerment for the intervention group. The differences between the two groups were statistically significant in the SCC scores (p<0.037). A significant difference was observed between the mean of the SCC score of the intervention group before and after the empowering (p < 0.0001). While, no significant changes were observed in the control group, before and after the study (p= 0.44). Empowering spiritual care skills in nursing students develops the quality of care in patients, which requires more attention in the educational curriculum.*

Keywords: *holistic care; spiritual care; competence; empowerment program; nursing students*

INTRODUCTION

A holistic attitude is a dynamic way of educating an individual with a holistic view, and the nursing profession is always focused on caring for a person as a whole and covering the physical, mental, social, and spiritual dimensions of a person [1]. Along with the physical and mental dimensions, the spiritual dimension is considered an important factor [2] and it is the basis that all principles, ideas, thoughts, beliefs, choices, actions, and final goals of a person are focused on it [3]. Considering this important human dimension and providing comprehensive care will promote the recovery and well-being of patients [4]. Hence, spiritual care is an integrated section of the nursing process [5]. Spiritual care contains religious and non-religious skills [6]. The religious skills contain such things as patient accompaniment in worship and provision of the necessary requisites for religious ritual, talking with him about God, clarifying the patient's relationship with God, applying religious books, and referring to religious institutions. The non-religious skills also contain relationship skills, empathy, respect, counseling, emotional support of people, and encouraging the client to express feelings and avoid negative thoughts [7]. The correct implementation of spiritual care requires having the necessary skills in this field [8]. This competence is very important for nurses and nursing students because the patients' spiritual needs become apparent when disease or crisis occurs [9]. Spiritual competence empowers nurses and increases their knowledge and skills to nurture hope, meaning, and purpose in patients [2]. During the course of the disease, nursing students are admitted to the private domain of patients, along with health workers, so they should be able to deal with their spiritual issues [10]. Students have different cultural and spiritual views, beliefs, and values than current nurses [11], and institutionalization of ethical principles among students and preparing them for future professional life is an important part of university responsibility. The task of universities is to organize the educational environment in accordance with the culture and religion of the country and the needs of the community [12]. Studies show that the spiritual competence of nurses and nursing students is not in good condition [11, 13-15]. A study showed that only 42% of nurses in the clinic pay attention to the patient’s spiritual needs [13]. Also, Ross et al. (2014) reported that only 25% of nursing students are qualified to perform spiritual care [16], and most nursing students in clinical practice ignore spiritual care [17]. Although nurses are motivated to become qualified in spiritual care [18] and nursing students value it [11], they do not implement spiritual care, and lack of attention to spirituality in undergraduate programs is stated as the predominant obstacle to the lack of competence in implementation spiritual care [19-21]. The results of the studies show that the nursing curriculum needs to integrate spirituality and spiritual care more than ever [22, 23] so that nurses become more aware of the patients’ spiritual needs [2]. Culatto and Summerton (2015) reported that spirituality is an important part of the curriculum before and after a clinical period, and 64.2% of educational institutions considered spirituality a valuable and significant part of education, and only 14.3% considered this part worthless [24]. Nursing literature also recognizes the need for nurses' empowerment in the field of spiritual care [25-27]. However, so far this issue has not been formally and explicitly included in nursing education programs [16]. Spiritual empowerment can improve students' attitudes and awareness about the spirituality of patients, assess spiritual needs, respond differently to their needs, the ability to refer patients, and their communication skills [28,29]. It was also found in another qualitative study that spiritual care education had a positive effect on their personal, academic, and professional lives [30]. In spite of the benefits of spirituality education, a review study by Cooper et al. (2013) noted its negative effects, such as the concern and the sense of coercion in changing personal opinions about spirituality [31], and in another study, little effect of spiritual care education was found on students' attitude towards spirituality and communication skills [32]. Few studies have been done on the form and manner of empowering spirituality [33]. Therefore, it is necessary to conduct numerous studies to evaluate the benefits of empowering methods in the field of spirituality [34]. The purpose of this study was to investigate the effect of an empowering plan on the competence of implementation of spiritual care in nursing students.

MATERIALS AND METHODS

The present study is a randomized control clinical trial that was performed on senior nursing students of the Faculty of Nursing and Midwifery of Kashan University of Medical Sciences.

Participants and data sampling

The sample size was estimated to be 30 in each group based on the mean and standard deviation of the previous study [28, 29] at a 95% confidence level and 80% test capacity ($\alpha = 0.95$, $\beta = 0.2$, $s1 = 10$ and $s2 = 10$). Sampling in the first stage was simply random so the samples were selected from the list of senior nursing students of the faculty using the random number table. Then, students were randomly assigned to two intervention (30) and control (30 people) groups by block randomization (four blocks). Inclusion criteria included students who were studying in the seventh and eighth semesters, were not guests and free from academic probation or transfer, had no known physical and psychological problems, and were satisfied with the research. Students who were reluctant to continue to cooperate at each stage of the research, had severe crises (like the death of a close family member, divorce, separation, and quarrel with the spouse), and had two sessions or more absences in the classes, were excluded from the study.

Procedure

The researchers gave information on the objectives, type, advantages, and confidentiality of the study to the students. If they were willing to collaborate in the study, written informed consent was completed and the study instrument was self-reported by them. The samples were then assigned to intervention and control groups. The intervention group was under the empowering plan. The intervention method was such that the students participated in a group and in a single month in seven 60-minute sessions. The control group was trained under the former and routine curriculum of the university. Educational pamphlets about care were also provided. In the final of the study (one month after starting the study), the study tool was completed by the samples again.

Intervention

The empowerment content of the present study is taken from past studies [29,33,35-37] and consists of spiritual subjects such as the description of spirituality and spiritual care, assessment and implementation of spiritual care, communication skills, respect for human dignity, individual support, counseling, hope therapy, and betterment the quality of life, which was explained and taught in the form of lectures and small group discussions (Box 1). This content was confirmed by 10 experts and faculty members who had the awareness and experience in this background.

Data Collection

The study instrument consists of two sections of individual social information inventory including 9 items containing age, gender, marital status, semester, accommodation status, interest in the subject of spirituality, passing the course of spiritual care, participation in the ethics seminar or workshop, and the degree of personal religiosity and the scale spiritual competence.

Box 1: Subjects of the training plan

Session 1:
- The description of spiritual health and its dimensions
- Acceptance of life and relationship with God, self, society, and the environment
- The expression of the integrity of the biological, psychological, and social components
- Essential characteristics of spirituality
- Differences and similarities between spirituality and religion
- Explain spirituality and spiritual care
- Religious and non-religious care

Session 2:
- Types of spiritual care (personal, procedural, cultural, and evangelical)
- Essential skills for performing its
- Spiritual distress, the influence of disease on individual life
- Detect meaning and goal of life
- The role of hope in patient spirituality
- Facilitate coping and adaptation strategies used by patients during illness

Session 3:
- Dimension of professionalism and betterment of the quality of life
- Obstacles to the implementation of its
- Strategies to improve its

Session 4:
- Assessment and implementation of its
- The patients’ spiritual needs during illness and how to assess them
- How to provide spiritual care by nurses
- The nursing process in spirituality
- Communication skills

Session 5:
- Communication techniques, trust building, and patient acceptance
- Active listening
- How to express feelings

Session 6:
- Importance of human dignity
- Efficacy of observance of privacy in patient’s spirituality
- Paying attention to spiritual care in the charter of patient rights
- Personal support
- Counseling and referral

Session 7:
- Attention and support of religious rituals
- Religious and spiritual referral
- Protective presence

The Spiritual Care Competence Scale (SCCS) was designed by Van Leeuwen & Cusveller (2009). This scale has 6 dimensions, the first dimension is "assessment and implementation of spiritual care" (Questions 1-6), the second dimension "professionalism and betterment of the quality of spiritual care" (Questions 7-12), the third dimension "personal support and patient counseling" (Questions 13-18), the fourth dimension "referral" (Questions 19-21), the fifth dimension "attitude towards patients' spirituality" (Questions 22-25) and finally the sixth dimension is "communication" (Questions 26-27) that the responses were ranked according to the 5-point Likert scale (fully agree, to fully disagree). The total score of this scale is between 27 and 135 and it has three grades. A score of 27 to 62 indicates a low level, a score of 63 to 98 indicates an average level and a score of more than 98 indicates a high level of spiritual competence. The validity and reliability of this instrument were investigated by Van Leeuwen et al. In 2009, the Cronbach's alpha coefficient for the sub-scales was between 0.56 to 0.82 and the mean inter-item correlation ((MIIC ≥ 0.25) was reported as an acceptable level of internal consistency or reliability [38]. The validity and reliability of this scale have been confirmed in Iran. In the study of Nasehi et al. (2013), the Cronbach's alpha coefficient was 0.78 and in the other study, the Cronbach's alpha coefficient for the whole instrument was 0.77, and for the subcategories have been reported between 0.65 and 0.85 [8,10].

Data Analysis

Data analysis was performed using SPSS software version 16 (SPSS Inc., Chicago, IL, USA). The Kolmogorov-Smirnov test was used to determine the normal distribution of the data. Descriptive statistics (i.e., mean, standard deviation, frequency, and percentage) were calculated. Fisher and t-tests were used to compare demographic variables in the two groups. The independent-sample t-test was also used to examine the differences between the competence of spiritual care mean scores, and the subscale mean scores within the two groups at the beginning and the final of the study. In addition, a paired-sample t-test was used to compare the changes in the competence of spiritual care mean scores of the individual groups at the beginning and the final of the study. The significance level was considered less than 0.05 in all tests.

RESULTS

Out of 60 participants in this study, eight persons in the intervention group and five persons in the control group were excluded from the analysis due to irregular attendance at training sessions and incomplete answers in the post-test instrument, respectively. Finally, the data of 47 samples were analyzed (Figure 1).

The mean age of participants was 22.43 ± 0.85. About 25.5% of the participants in the intervention group and 36.2% in the control group were female.

Lost to follow-up: Discontinued intervention (n= 5)
Analysis
Analysed (n= 22)
Analysed (n= 25)

The results showed that there was no significant difference between the two groups' demographic variables, including age, semester, sex, marital status, accommodation status, interest in the subject of spirituality, and attending spiritual care of patient course ($p > 0.05$) (Table 1). The results obtained from conducting independent sample t-tests revealed that there was no significant difference between the mean scores of spiritual care competence and its subscales for the two groups at the beginning of the study ($p > 0.05$) (Table 2). However, the mean score of spiritual care competence (104.9 ± 9.7 for the intervention group, and 97.4 ± 14 for the control group), was significantly increased post-intervention for the intervention group. The differences between the two groups were statistically significant in both the overall spiritual care competence scores ($p < 0.037$) and across two of the subscales, including "assessment and implementation of spiritual care" and "professionalism and betterment of the quality of spiritual care" ($p < 0.05$) (Table 3). Using paired t-tests, we found that spiritual care competence and its subscales, including "assessment and implementation of spiritual care", "professionalism and betterment of the quality of spiritual care", "personal support and patient counseling" and "referral" in the intervention group were significantly different before and after the spiritual education ($p < 0.0001$). There was no significant difference between the mean scores of the spiritual care competence and its subscales in the control group at the beginning and the final of the study ($p > 0.05$) (Table 4).

DISCUSSION

The purpose of this study was to investigate the efficacy of empowerment programs on the competence of implementation of spiritual care in nursing students it showed that spiritual empowerment generally increases the competence of implementation of nursing students' spiritual care, but its impact on the dimensions of "assessment and implementation of spiritual care", "professionalism and betterment of the quality of spiritual care", "personal support and patient counseling" and "referral" are more than the dimensions of "attitude toward patients' spirituality" and "communication skills". The findings of this study are consistent with the findings of studies with the aim of determining the efficacy of the empowering plan in betterment of the competence of providing spiritual care by nursing students [32], the effectiveness of an educational intervention in the ability to perform spiritual care and spiritual well-being of undergraduate and postgraduate students [39], the effectiveness of simulated-spiritualized training in implementation of spiritual care for nursing students [28], and the changes in the spiritual experiences of medical and nursing students before and after a period of clinical and spiritual care [40]. Also, in a qualitative study, the survey of experiences of nursing students after the course of spiritual care showed that spirituality had a positive effect on their personal, academic, and professional lives, and led to increased self-awareness, individual development, knowledge about spirituality and spiritual care, sensitivity to the patient's spiritual needs, familiarity with adaptation methods, and providing holistic care [33]. In fact, students who are trained in spirituality, realize the concept of spirituality and give more notice to the patient's spiritual needs [41]. Increasing their moral sensitivity and ethical decision-making ability in clinical settings [29], in addition, they do it in their daily routines. Concerning the cause of the effect of the empowerment plan, the following may be mentioned: since spiritual awareness is prior to the spiritual assessment of patients [41], spirituality empower-ing by increasing awareness of students about patients' spiritual needs and improving their attitude toward spirituality, provides the required competencies in assessing spiritual needs, responding differently to needs, referring patients and communication skills [28]. Empowering also leads to an increase in understanding of the value of spirituality [40] and the ability to provide spiritual care to nursing students in the future.

The method of spiritual empowerment has also been effective in the efficacy of education. According to Taylor, the best method of spiritual care education is to induce a positive attitude and compassionate skills in order to create a sensitivity to spiritual care, which is not achieved except through student discussion [42]. In this study, students used the ideas of each other and recognized their and other's religious views to understand and develop spiritual self-awareness. In addition, inspirational stories were also assisted.

The reason for the low impact of the plan on some aspects of the competence of providing spiritual care, including the attitude toward spirituality and communication, is probably lack of work experience because spirituality is not only rooted in one's beliefs, but also rooted in his experience [4] and factors such as individual spirituality, degree of beliefs, experience, and age of individuals are associated with their attitude to spiritual care [43]. Of course, there is another point to consider that communication is more effective in responding to this topic and is also a kind of research limitation, and it is a self-report of students. Hence, the use of other instruments in assessing these skills is suggested. Considering the influence of the group discussion method, it is suggested that other active educational methods be evaluated and compared in subsequent studies to better spiritual care education and to choose the best em-powering method for spirituality and spiritual care.

CONCLUSION

Based on the results, the empowerment plan is effective and useful in the field of spiritual care competence of nursing students. Therefore, authorities should pay more attention to the importance of empowering spiritual care to nursing students, because the more nursing students have knowledge of spiritual care is greater, the higher the quality of care provided to the patient. Nursing students need to be trained in a wider range of spiritual care skills and it is best to pay more notice to this topic in the nursing educational curriculum. Valuing spiritual care and proper nurse-patient spiritual communication enriches the nursing profession increases nurses' job satisfaction and provides opportunities for better performance.

Conflicts of interest and sources of funding

The authors do not declare a conflict of interest. This article was funded and supported by the Deputy of Research, Kashan University of Medical Sciences, Grant No: 96216.

Authors' contribution

Conceptualization and supervision: KS and MA; Data collection: ZS, MH; Data analysis: MA; Writing-original draft and Writing-review & editing: ZS and MA; Final approval: All authors.

Acknowledgments

The researchers would like to thank the staff of the Faculty of Nursing and Midwifery of Kashan, Iran, and all the nursing students participating in the present study.

Ethics approval and consent to participate

This study was confirmed by the institutional review board and the ethics committee of the University (IR.KAUMS.NUHEPM.REC.1396.41). The objectives of the study were stated for all nursing students and informed written consent was obtained from them. All student's participation in this study was voluntary and they had the right to withdraw from the study at any time and stage of the study. Also, they were reassured that their personal information would remain confidential. The current research was registered with registration code IRCT20130721014086N11.

Abstract: *COVID-19 has not been adequately investigated in patients with psoriasis. We wanted to evaluate the effect of COVID-19 and COVID-19 vaccines on disease course in patients with psoriasis. We retrospectively reviewed the medical records of patients who were admitted for the treatment of psoriasis between March 2020 and May 2022. Afterward, patients were contacted by telephone call to collect data on COVID-19. This study included 257 patients, 118 females, and 139 males. 238 (92.6%) patients were vaccinated against COVID-19. The mean age of the vaccinated and unvaccinated patients was 49.23±14.60 and 40.37±11.66 years, respectively (p=0.010). Exacerbation of psoriasis after COVID-19 vaccination was detected in 32 (13.4%) patients. 114 (44.4%) patients had been diagnosed with COVID-19 and 18.4% of them stated exacerbation of psoriasis after COVID-19. No association was detected between COVID-19 and having an accompanying disease and psoriasis treatment (p=0.843, p=0.845, respectively). Hospitalization was required in 12 (10.5%) patients. Unvaccinated patients with psoriasis were significantly younger than those who were vaccinated. Exacerbation of psoriasis was reported in 13.4% of vaccinated patients and in 18.4% of patients after COVID-19. Nevertheless, accompanying disease and conventional or biological agent treatment were associated neither with COVID-19 nor COVID-19-related hospitalization.*

Keywords: *COVID-19; psoriasis; vaccine*

INTRODUCTION

Psoriasis is a chronic inflammatory skin disease that affects 2-3% of the general population [1]. Psoriasis may be triggered by infections and various vaccines such as influenza and tetanus-diphtheria vaccines [2]. Recently, exacerbation and onset of psoriasis have been reported after Coronavirus disease 2019 (COVID-19) and vaccination against COVID-19 [3,4]. Common inflammatory cytokine production has been reported both in patients with psoriasis and in patients with COVID-19 or vaccinated against COVID-19 [5,6]. However, the exact mechanism of exacerbation of psoriasis after vaccination against COVID-19 has not been clearly understood yet. Increased Th17 response in psoriasis has also been detected in patients with severe COVID-19. Therefore, mRNA COVID-19 vaccines may lead to exacerbation of psoriasis by inducing Th17 cells [7].

In addition, the course of COVID-19 in patients with psoriasis remains controversial. It has been suggested that psoriasis might be a risk factor for severe COVID-19 since psoriasis comorbidities such as hypertension, diabetes, and cardiovascular disease have been associated with poor prognosis of COVID-19 [8]. Increased serum level of angiotensin-converting enzyme (ACE) has been reported in psoriasis patients with comorbidities such as cardiovascular disease and atherosclerosis. Therefore, hyperactivity of ACE in COVID-19 may lead to susceptibility to cardiovascular events in psoriasis patients with COVID-19 [9].

Moreover, data on the association between immune-suppressive treatment and increased risk for COVID-19 are inadequate and it is a matter of debate that cessation of immunosuppressive treatment and biological agents in psoriasis patients with COVID-19 is required or not [6,8]. On the other hand, vaccination against COVID-19 is of utmost importance in patients with psoriasis, especially in those under immunosuppressive treatment. Nevertheless, vaccination against COVID-19 in patients with psoriasis has not been adequately investigated [10]. Within this study, COVID-19 vaccination status and the effect of COVID-19 and Pfizer-BioNTech and Sinovac-CoronaVac COVID-19 vaccines on disease course were evaluated in patients with psoriasis.

MATERIALS AND METHODS

Gazi University Ethics Committee approval was obtained before this study (approval number: 2022-700). We retrospectively reviewed the medical records of patients who were admitted for the treatment of psoriasis between March 2020 and May 2022. Patients aged 18 years and over with complete data were included in the study. The exclusion criteria were pregnancy, lactation, and receiving any vaccines other than COVID-19 such as the flu shot. Data on age, gender, psoriasis type, psoriasis duration, psoriatic arthritis, past medical history, and psoriasis treatment were evaluated. Afterward, patients were contacted by telephone call to collect the data on COVID-19 vaccination status, vaccine type, vaccine dose, effect of COVID-19 vaccines on psoriasis, time to initiation of exacerbation of psoriasis after vaccination, other cutaneous side effects of vaccines, diagnosis of COVID-19, effect of COVID-19 on psoriasis, time to initiation of exacerbation of psoriasis after COVID-19, other cutaneous effects of COVID-19 and requirement of hospitalization. Exacerbation of psoriasis was regarded as an increase in the size and number of the psoriasis lesions.

Statistical analysis was performed using SPSS version 20.0. Data were presented as mean ± standard deviation or median (interquartile range) for quantitative variables, counts, and percentages for categorical variables. Differences between the groups were evaluated by using the chi-square test and Mann-Whitney U test. P values less than 0.05 were considered statistically significant.

RESULTS

This study included 257 patients, 118 (45.9%) females and 139 (54.1%) males. The mean age of the patients was 48.57±14.57 years (range: 18-84 years). 233 (90.7%) patients had psoriasis vulgaris, 14 (5.4%) had palmoplantar pustular psoriasis, 7 (2.7%) had generalized pustular psoriasis, 1 (0.4%) had inverse psoriasis, 1 (0.4%) had nail psoriasis and 1 (0.4%) had guttate psoriasis. The mean psoriasis duration was 17.56±12.36 years (range: 1-54 years). Psoriatic arthritis was observed in 70 (27.2%) patients. The past medical history was unremarkable in 140 (54.5%) patients. However, hypertension was detected in 60 (23.3%) patients, diabetes in 36 (14%), chronic hepatitis B virus infection in 20 (7.8%), coronary artery disease in 16 (6.2%), hypothyroidism in 11 (4.3%), hyperlipidemia in 11 (4.3%), chronic obstructive pulmonary disease in 5 (1.9%), chronic renal disease in 5 (1.9%) and asthma in 5 (1.9%) patients. Malignancies such as thyroid, bladder, non-small cell lung, and breast cancers were detected in 5 (1.9%) patients, rheumatic diseases such as rheumatoid arthritis, ankylosing spondylitis, gout, and Sjögren's syndrome in 4 (1.6%) patients, benign prostatic hyperplasia in 4 (1.6%), chronic venous insufficiency in 2 (0.8%) and migraine in 2 (0.8%) patients. 129 (50.2%) patients were treated with biological agents. 52 (20.2%) patients received ustekinumab, 35 (13.6%) received interleukin-17 (IL-17) inhibitors such as secukinumab and ixekizumab, 34 (13.2%) received tumor necrosis factor-α (TNF-α) inhibitors such as adalimumab, etanercept, infliximab and certolizumab pegol, 8 (3.1%) patients received IL-23 inhibitors such as guselkumab and risankizumab. In addition, 93 (36.2%) patients were treated with methotrexate, 27 (10.5%) with acitretin, 5 (1.9%) with cyclosporine, and 3 (1.2%) with narrowband ultraviolet B therapy.

238 (92.6%) patients were vaccinated against COVID-19 whereas, 19 (7.4%) patients were unvaccinated (Table 1). The mean age of the vaccinated and unvaccinated patients was 49.23±14.60 and 40.37±11.66 years, respectively (p=0.010). 114 (44.4%) patients received Pfizer-BioNTech, 77 (30%) patients received both Pfizer-BioNTech and Sinovac-CoronaVac, 47 (18.3%) patients received Sinovac-CoronaVac COVID-19 vaccines. The mean age of the patients vaccinated with only Pfizer-BioNTech and only Sinovac-CoronaVac COVID-19 vaccine was 44.12±12.72 and 49.49±15.19 years, respectively (p=0.023). The mean psoriasis duration of the patients vaccinated with only Pfizer-BioNTech and only Sinovac-CoronaVac COVID-19 vaccine was 14.75±11.29 and 19.72±13.23 years, respectively (p=0.017). 29 (61.7%) patients vaccinated with only Sinovac-CoronaVac had at least one accompanying disease whereas, 39 (34.2%) patients vaccinated with only Pfizer-BioNTech had at least one accompanying disease (p=0.002). 8 (17%) patients vaccinated with only Sinovac-CoronaVac had diabetes whereas, 5 (4.4%) patients vaccinated with only Pfizer-BioNTech had diabetes (p=0.007). Among 191 (74.3%) patients who received Pfizer-BioNTech COVID-19 vaccine, 93 (36.2%) received 2 doses, 68 (26.5%) received 3 doses, 29 (11.3%) received 1 dose and 1 (0.4%) received 4 doses of vaccine. Among 124 (48.2%) patients who received Sinovac-CoronaVac COVID-19 vaccine, 88 (34.2%) received 2 doses, 16 (6.2%) received 4 doses, 14 (5.4%) received 3 doses, 4 (1.6%) received 1 dose and 2 (0.8%) received 5 doses of vaccine. No accompanying disease has been detected in 22 (73.3%) patients who were unvaccinated or received only a single dose of vaccine and in 118 (52%) patients who received two or more doses of vaccine (p=0.027). 206 (86.6%) patients reported no effect of COVID-19 vaccines on psoriasis, however, 32 (13.4%) patients reported exacerbation of psoriasis after COVID-19 vaccines. Among them, 24 (75%) received Pfizer-BioNTech, 7 (21.9%) received Sinovac-CoronaVac and 1 (3.1%) received both Pfizer-

BioNTech and Sinovac-CoronaVac COVID-19 vaccines. Exacerbation of psoriasis lesions was reported in 28 (87.5%) patients, generalized psoriasis lesions in 3 (9.4%) patients, and exacerbation of nail involvement in 1 (3.1%) patient (Table 2). The median time to initiation of symptoms after COVID-19 vaccination was 15 (25.25) days. Moreover, 1 (0.4%) patient had urticaria, 1 (0.4%) had papules and pustules on soles and 1 (0.4%) had COVID arm following Pfizer-BioNTech COVID-19 vaccination.

Table 1: Vaccination status of patients with psoriasis against COVID-19

	Vaccinated	**Unvaccinated**	**P value**
Patients, n (%)	238 (92.6%)	19 (7.4%)	
Mean age ± SD (years)	49.23±14.60	40.37±11.66	0.01
Administered vaccine, n (%)	Pfizer-BioNTech, 114 (44.4%) Pfizer-BioNTech and Sinovac-CoronaVac, 77 (30%) Sinovac-CoronaVac, 47 (18.3%)		
	Pfizer-BioNTech	**Sinovac-CoronaVac**	
Mean age ± SD (year)	44.12±12.72	49.49±15.19	0.023
Mean psoriasis duration ± SD (year)	14.75±11.29	19.72±13.23	0.017
Accompanying disease, n (%)	39 (34.2%)	29 (61.7%)	0.002
Diabetes, n (%)	5 (4.4%)	8 (17%)	0.007

COVID-19: Coronavirus disease 2019, SD: Standard deviation. Vaccination with Pfizer-BioNTech was more common in younger patients and patients with shorter psoriasis duration compared to vaccination with Sinovac-CoronaVac COVID-19 vaccine (p=0.023, p=0.017, respectively)

Table 2: The effect of COVID-19 and Pfizer-BioNTech and Sinovac-CoronaVac COVID-19 vaccines on patients with psoriasis

Exacerbation of psoriasis after vaccines, n (%)	32 (13.4%)
Vaccine type, n (%)	Pfizer-BioNTech, 24 (75%) Sinovac-CoronaVac, 7 (21.9%) Pfizer-BioNTech and Sinovac-CoronaVac, 1 (3.1%)
Effect of vaccines on psoriasis, n (%)	Exacerbation of the lesions, 28 (87.5%) Generalized lesions, 3 (9.4%) Exacerbation of nail involvement, 1 (3.1%)
Initiation of the symptoms after vaccination, median time (IQR)	15 (25.25) days
Cutaneous effects of Pfizer-BioNTech vaccine, n (%)	Urticaria, 1 (0.4%) Papules and pustules on soles, 1 (0.4%) COVID arm, 1 (0.4%)
Exacerbation of psoriasis after COVID-19, n (%)	21 (18.4%)
Time to onset of COVID-19 and exacerbation of psoriasis, (mean ± SD)	11.83±9.59 days
COVID-19 related hospitalization, n (%)	12 (10.5%)

COVID-19: Coronavirus disease 2019, IQR: Interquartile range, SD: Standard deviation. Exacerbation of psoriasis after vaccines was reported in 32 (13.4%) patients. Among them, 24 (75%) patients received the Pfizer-BioNTech COVID-19 vaccine

114 (44.4%) patients had been diagnosed with COVID-19 whereas, 143 (55.6%) patients never had the infection. No statistically significant difference was observed between patients who had been diagnosed with COVID-19 and those who never had COVID-19 in age, gender, psoriasis duration, having an accompanying disease, psoriatic arthritis, hypertension, and diabetes (p=0.660, p=0.154, p=0.254, p=0.843, p=0.093, p=0.194, p=0.726, respectively). 21 (18.4%) patients stated exacerbation of psoriasis after COVID-19, however, 93 (81.6%) patients stated no effect of COVID-19 on psoriasis. The mean time between the onset of COVID-19 and exacerbation of psoriasis was 11.83±9.59 days (range: 1-30 days). Exacerbation of psoriasis after COVID-19 was detected in 6 (37.5%) patients who reported exacerbation of psoriasis after COVID-19 vaccines and in 11 (12.5%) patients who reported no effect of vaccines on psoriasis (p=0.013). Besides psoriasis, none of the patients developed any skin lesions which might be associated with COVID-19. No statistically significant difference was observed between patients who had been diagnosed with COVID-19 and those who never had COVID-19 in psoriasis treatment such as biological agents and conventional medication, in biological agents received such as anti-TNF-α, anti-IL-17, anti-IL-12/23 and anti-IL-23 agents and in vaccination status or vaccine type (p=0.845, p=0.274, p=0.452, p=0.694, respectively). 12 (10.5%) patients were hospitalized for COVID-19. None of the patients required

treatment in an intensive care unit. No statistically significant difference was observed between patients who were hospitalized and did not require hospitalization for COVID-19 in age, gender, psoriasis duration, having an accompanying disease, hypertension, diabetes, psoriatic arthritis, treatment with conventional and biological agents, and vaccination status (p=0.462, p=0.587, p=0.972, p=0.309, p=0.615, p=0.705, p=0.473, p=0.249, p=0.309, respectively).

DISCUSSION

Vaccination of patients with psoriasis is crucial in the fight against COVID-19 since immunosuppressive treatment leads to predisposition to infections and psoriasis patients with comorbidities such as metabolic syndrome may be more vulnerable to severe COVID-19 [11]. Therefore, vaccination against COVID-19 is recommended for all psoriasis patients without vaccine allergies, especially for those who receive immunosuppressive treatment [12]. However, it has been suggested that safety concerns might lead to decreased vaccination rates in patients with psoriasis [13,14]. In the United States, Gondo et al. reported that 35.9% of patients with psoriasis were unlikely to get the COVID-19 vaccine. Gondo et al. reported no association between age, gender, having comorbid disease, and being likely to get the COVID-19 vaccine [15]. Sotiriou et al. stated that younger patients with psoriasis, females, patients under biological agent treatment, patients with diabetes, chronic obstructive pulmonary disease, and malignancy had positive beliefs towards COVID-19 vaccines. Concerns about the safety and effectiveness of vaccines and the risk of the exacerbation of psoriasis led to unwillingness to vaccination among patients with psoriasis [16]. Wang et al. reported that 68.9% of patients with psoriasis were vaccinated against COVID-19 in China. Young age, anti-IL-17 treatment, psoriatic arthritis, pustular psoriasis, erythrodermic psoriasis, anxiety, and depression were related to unvaccinated patients [13]. Within this study, 92.6% of the patients with psoriasis were vaccinated. Unvaccinated patients were younger than those who were vaccinated (p=0.010). In addition, most (73.3%) of the psoriasis patients who were unvaccinated or received only a single dose of vaccine had no accompanying systemic disease. Vaccination with Pfizer-BioNTech was more common in younger patients and patients with shorter psoriasis duration compared to vaccination with Sinovac-CoronaVac COVID-19 vaccine (p=0.023, p=0.017, respectively). However, vaccination with Sinovac-CoronaVac was more common in patients with diabetes or at least one accompanying disease compared to vaccination with the Pfizer-BioNTech COVID-19 vaccine (p=0.007, p=0.002, respectively).

Despite the importance of vaccination, data on the safety of COVID-19 vaccines in patients with psoriasis are scarce [17]. New onset and exacerbation of psoriasis have been reported following the administration of COVID-19 vaccines [18]. COVID-19 vaccines have been associated with plaque, guttate, pustular, nail, and erythrodermic psoriasis [5,18-21]. However, the effect of COVID-19 vaccines on psoriasis has not been clearly identified [11]. Wang et al. reported deterioration of psoriasis in 21% of patients and rash and itching in 4% of patients after COVID-19 vaccination [13]. El-Qushayri et al. reviewed the published data on patients who experienced flare-ups of psoriasis due to COVID-19 vaccines. The flare-up of psoriasis was reported in 51 patients, 55% of whom were female after Pfizer-BioNTech, Oxford-AstraZeneca, Moderna, Sinovac-CoronaVac and Covaxin COVID-19 vaccines [17]. Wu et al. reviewed the data on 279 patients with flare-ups of psoriasis following COVID-19 vaccines. Wu et al. reported slight female predominance and plaque psoriasis as the most commonly observed psoriasis type. The time to onset of the flare was 1 to 90 days and the Pfizer-BioNTech COVID-19 vaccine was the most commonly implicated one [22]. Within this study, 32 (13.4%) patients reported exacerbation of psoriasis after COVID-19 vaccines. Exacerbation of skin lesions was the most common finding (87.5%) followed by generalized skin lesions (9.4%) and exacerbation of nail involvement (3.1%). Pfizer-BioNTech COVID-19 vaccine was implicated in most of the cases and the median time to onset of symptoms after COVID-19 vaccination was 15 (25.25) days. Urticaria, papules, and pustules on soles and COVID arm were the other cutaneous side effects detected after the administration of the Pfizer-BioNTech COVID-19 vaccine.

Moreover, COVID-19 has been implicated in the exacerbation and onset of psoriasis [23]. It has been suggested that the synthesis of cytokines such as TNF-α, IL-17, and IL-23 due to activation of toll-like receptor 3 in patients with COVID-19 might trigger psoriasis [23]. For instance, Rouai et al. reported a patient with guttate psoriasis which was started 5 days after recovery from COVID-19 [23]. Shah et al. reported exacerbation of psoriasis following COVID-19 in 3 patients who were well-controlled under treatment with ustekinumab, apremilast, and risankizumab [4]. Erythroderma has also been reported in patients with psoriasis due to COVID-19 [24-26]. Furthermore, concerns have been raised on whether immunosuppressive treatment in patients with psoriasis might negatively affect the course of COVID-19, especially in those with comorbidities [27]. Kridin et al. reported no difference in the risk for COVID-19 and hospitalization and mortality due to COVID-19 in patients with psoriasis treated with IL-17 inhibitors compared to patients who received methotrexate or non-systemic treatments [27]. Yan et al. reported COVID-19 in 33.5% of 173 patients with psoriasis and psoriatic arthritis. Requirement of hospitalization and intensive care stay was detected in 19% and 10% of patients, respectively. Yan et al. suggested that hypertension was associated with severe COVID-19 whereas, treatment with IL-12/23 and IL-23 inhibitors led predisposition to COVID-19. However, methotrexate, apremilast, TNF-α, and IL-17 inhibitor treatment did not affect COVID-19 outcomes [28]. Nevertheless, a meticulous approach is recommended in psoriasis patients treated with biological agents [29]. Within this study, 114 (44.4%) patients had been diagnosed with COVID-19. No association was detected between COVID-19 and age, gender, having an accompanying disease, psoriasis treatment such as biological agents and conventional medications, COVID-19 vaccination status, and vaccine type ($p=0.660$, $p=0.154$, $p=0.843$, $p=0.845$, $p=0.452$, $p=0.694$, respectively). 21 (18.4%) patients stated that COVID-19 exacerbated their psoriasis and the mean time to onset of symptoms was 11.83±9.59 days. Exacerbation of psoriasis after COVID-19 was more frequent in patients who reported exacerbation after COVID-19 vaccines. This result may indicate a common mechanism of action of both COVID-19 and COVID-19 vaccines on psoriasis flare. Hospitalization for COVID-19 was required in 12 (10.5%) patients. No association was detected between the requirement of hospitalization and age, having an accompanying disease, treatment with conventional or biological agents, and vaccination status ($p=0.462$, $p=0.309$, $p=0.249$, $p=0.309$, respectively).

CONCLUSION

The rate of vaccination against COVID-19 in patients with psoriasis was 92.6%. Besides the high vaccination rate, unvaccinated patients with psoriasis were at a younger age. Most (44.4%) of the patients were vaccinated with the Pfizer-BioNTech COVID-19 vaccine. However, age, psoriasis duration, having an accompanying disease and diabetes affected the preferred vaccine type. 13.4% of the patients stated exacerbation of psoriasis after vaccination which more commonly occurred after the administration of the Pfizer-BioNTech COVID-19 vaccine. COVID-19 exacerbated psoriasis in 18.4% of the patients. Nevertheless, having an accompanying disease and treatment with conventional medications or biological agents were associated neither with COVID-19 nor hospitalization due to COVID-19. Our study is noteworthy in that it included psoriasis patients vaccinated with both Pfizer-BioNTech and Sinovac-CoronaVac COVID-19 vaccines. The results will hopefully contribute to the literature on the effect of COVID-19 and COVID-19 vaccines on patients with psoriasis, which has not been clearly elucidated yet.

Abstract: *Cervical cancer is a major cause of morbidity and mortality among women. It is the fourth most commonly diagnosed cancer in females. Screening strategies such as colposcopy can cause anxiety, discomfort, and pain in patients during this procedure and poor quality of life. The aim of this study was to evaluate the effect of psychoeducation on pain perception and anxiety in women undergoing colposcopy. This randomized clinical trial included 60 women, candidates for colposcopy referred to the surgical clinic of Kashan, Iran. The patients were randomly assigned into two groups: the experimental group, which received 60 minutes of psychoeducation, and the control group. Data were collected with the Spielberger anxiety inventory and visual analog score of pain and were analyzed using independent and dependent t-tests, Chi-square, and co-variance performed with SPSS version 16. The means of anxiety scores were significantly decreased post-psychoeducation in the intervention group, and the differences between the two groups were statistically significant in the anxiety scores ($P < 0.0001$). A significant difference was observed between the mean anxiety scores of the intervention group prior to and after the psychoeducational program (PEP) intervention (99.50 ± 5.28 vs. 84.89 ± 8.80) ($P < 0.0001$). No significant changes were observed in the control group pre- and post-psychoeducation ($P > 0.05$). There was no statistically significant difference between the mean pain score between the study and the control group at the end of the study ($P = 0.17$). Psychoeducation resulted in reduced anxiety in women undergoing colposcopy. Therefore, it is recommended to consider this intervention as a suitable and effective complementary, non-invasive, low-cost method to reduce anxiety in these patients.*

Keywords: *anxiety; colposcopy; pain; psychoeducation, woman*

INTRODUCTION

Cervical cancer is a major cause of morbidity and mortality among women. It is the fourth most commonly diagnosed cancer in females [1]. According to global estimates from 2008, there are approximately 530,000 new cases of cervical cancer and it is responsible for 275,000 deaths annually [2]. Screening strategies such as colposcopy have successfully decreased cervical cancer incidence and mortality [3]. Colposcopy is the visual inspection of the cervix under magnification and is one of the first steps in the diagnostic workup of women with abnormal cervical cytology [4]. Like any other medical intervention, colposcopy can cause anxiety, discomfort, and pain in patients during this procedure. High anxiety during colposcopy can lead to a more difficult procedure for the doctor and the patient, as well as a lack of follow-up for the next steps [5].

Studies have reported long-term anxiety in the majority of women after colposcopy [6]. Although in these patients increased anxiety can result in impairment of health-related quality of life [5].

Anxiety is defined as a non-specific, unpleasant feeling of fear and discomfort, associated with a perceived danger, feelings of powerlessness, and prolonged tension in preparation for the expected danger/event [7]. General anxiety caused by the possibility of having cancer can be troublesome for some patients and high levels of anxiety before colposcopy can have adverse consequences, including pain and discomfort during the procedure and a high rate of loss to follow-up various interventions such as group educational counseling, and information leaflets. Listening to music during colposcopy and video colposcopy have been used to reduce anxiety during colposcopy examinations [7-11].

A majority of the studies on PEPs have been conducted on patients with psychiatric disorders while being limitedly implemented in patients with medical disorders [12]. This study aimed to examine the effects of a PEP intervention on anxiety and pain in women undergoing colposcopy.

MATERIALS AND METHODS

This randomized controlled trial was conducted on 60 women candidates for colposcopy who were referred to the surgical clinic of Kashan, Iran, in 2019. According to previous studies, the sample size was determined to be 30 patients in each group. The patients were recruited into the study consecutively. The subjects who met the inclusion criteria were randomly allocated into experimental and control groups through a randomized block sampling method. Blocking is used to ensure that comparison groups will be generated according to a predetermined ratio, 1:1. Blocking be used to ensure a close balance of the numbers in each group for every block of eight participants, for example, four would be allocated to each arm of the trial

The inclusion criteria were the age of 20- 50 years, anxiety scores higher than 30, no history of colposcopy, absence of psychological disorders, and recent use of anti-anxiety drugs. The exclusion criteria were the occurrence of any acute or urgent medical or psychological upheaval, and the patient's decision to leave the study. A written informed consent was obtained from each participant.

Procedure

In addition to routine medical care, the experimental group received PEP intervention, which included discussions and training materials on skills for coping with anxiety and pain, with an emphasis on muscular relaxation techniques, as presented in Box 1. The STAI inventory was assessed before and after the PEP session in the intervention group.

Patients in the control group only received routine medical care, plus a training pamphlet from the patient care and health info (colposcopy) containing general information about the colposcopy. These patients answered the STAI inventory at the beginning of the recruitment and again after studying the pamphlet.

Both the intervention and control group's pain was assessed using the VAS scale after colposcopy.

Box 1: Content of the Psychoeducation session

Timing
5 to 10 minutes
Introducing the participants to each other, presenting the objectives of the procedure, and listening to the participants' feelings and problems.
10 minutes
Providing general information about the pap-smear, colposcopy, and its importance in cervical cancer prevention
5 minutes
Introducing the medical staff and providing information about the way the procedure is done by using educational photos, slides, and videos.
30 to 40 minutes
emotional support, through empathy, congruence, and unconditional positive acceptance and trying to encourage the patients in times of stress and improve their tendency to accept the importance of the procedure to decrease anxiety, Relaxation training and pain reduction techniques
10 minutes
informing the patients about possible side effects of the procedure

Instruments

A three-part instrument was used in this study. The first part contained questions about socio-demographic characteristics (the patient's age, marital status, family history of cancer, and delivery history). The second part of the instrument included a section on sociodemographics (such as educational level, employment status, parity, and smoking), State-Trait Anxiety Inventory (STAI), and VAS.

State-Trait Anxiety Inventory (STAI)

The State-Trait Anxiety Inventory (STAI) measures how a person feels in a certain situation at a certain period. It consists of 40 statements, and subjects are asked to indicate how they felt "at the moment", using a 4-point scale ranging from "not at all" to "very much so". The test is split into the State Anxiety Scale which is considered a subjective and temporary strain and the Trait Anxiety Scale (T-Anxiety) which evaluates relatively stable aspects of anxiety, including general states of calmness, confidence, and security. Total scores for each score obtained from the STAI range from 20 to 80. In this study, we classified the score into three categories: less than 40, low anxiety; between 40 and 60, average anxiety; and greater than 60, high anxiety class [13]. In the study, the reliability of the Persian version of STAI was determined from Cronbach's alpha which was 0.94 for the overall score [14]. The third part of the instrument was the VAS scale.

The VAS is a scale that measures the intensity of acute pain. It is a trustable, valid, and useable asset of measurement of pain in repeated measurements. The VAS is a scale of about 10 cm in length, and it can be utilized in a horizontal or vertical fashion. It starts with the "no pain" and ends with the "unendurable pain" definitions. The patient is asked to point out the choice of his/her perception of the intensity of his/her pain between two endpoints. The distance between the marked point and the outset of the line (0: no pain) is measured in centimeters and the result indicates the intensity of pain in a numeric fashion [15].

Ethical Considerations

Permission for this study was obtained from the ethics committee of the University of Medical Sciences. Ethical issues in this study involved the assurance of confidentiality and the anonymity of the participants. All participants were informed of the purpose and design of the study and understood that their participation was voluntary. Participants signed a written informed consent form before their participation.

Data Analysis

Data analysis was performed using SPSS software version 16 (SPSS Inc., Chicago, IL, USA). The normal distribution of the study data was tested with Shapiro-Wilk. The Student's t-test was performed for the analysis of the normally distributed permanent variants. The mean values were expressed using central tendency indicators: mean, median, standard deviation, 95% confidence interval of the mean, and range. A p-value less than 0.05 was considered statistically significant.

RESULTS

A total of 60 patients participated in the study. Eighty-nine percent of the women in the intervention group and 93% of the women in control group were married. The mean participant age was 39.19 ± 6.28. The majority of patients had a history of childbirth and had children and had a normal vaginal delivery (67.9% in the intervention group and 53.6% in the control group). The mean age in the intervention group was 39.07 years, the majority of whom had a diploma and university education (42.9%), while the mean age in the control group was 39.31 years, and the majority (44.8%) had a secondary and high school education. Twenty-five percent of the intervention group and 34.5 % of the control group reported a history of cancer in family members and friends. There were no significant differences between the intervention and control groups in age, marital status, education, family history, or parity.

The findings of the present study showed that PEP reduces anxiety levels in women undergoing colposcopy. Of the total participants, two in the intervention and one in the control group were excluded from the analysis due to incomplete answers on the post-test questionnaire. In total, the data from 57 patients were analyzed (Figure 1).

Both	5 (17.9)	4 (14.3)

** Mean ± Standard Deviation ** No. (%)*

No significant differences were found between the two groups in terms of socio-demographic variables (Table 1).

Analysis of covariance showed the means of overall anxiety and its attributes (state, trait) in the intervention group was significantly less than the control group at the end of the study (P<0.0001). Moreover, the t-dependent test results showed a significant decrease in overall anxiety score post-intervention (P<0.0001) while no significant decrease was seen in anxiety score in the control group at the end of the study (P>0.05). Using the independent t-test no significant differences were observed between the intervention and control groups in terms of the means of VAS score at the end of the study (Tables 2, 3).

DISCUSSION

This randomized trial showed that psychoeducation based on providing information and emotional support in a psychotherapeutic atmosphere and relaxation techniques before a colposcopy reduced anxiety among the participants. This finding is consistent with the results of Lungulescu, who studied the effects of PEP intervention on anxiety in women undergoing their initial breast cancer screening mammography [13]. Azogh et al. studied the effect of Psychoeducation on anxiety in subsequent pregnancy following stillbirth [16]. Ozturk et al. studied the effect of psychoeducation on anxiety and pain in patients with mastalgia [15]. Sancak et al have also reported that providing verbal and written information reduces anxiety in patients during third molar extraction [17]. PEPs combine methods of relaxation with psychological training, such as trying to convince patients to accept the importance of the procedure and muscle relaxation and pain relief techniques. Several studies have used single methods, such as anger management or relaxation, and reported positive effects. For instance, a systematic review study conducted confirmed the positive effect of relaxation techniques on reducing anxiety and depression among older adults [18]. Some studies [19, 20] used relaxation and distraction in patients with cardiac disorders and post-cardiac surgery and reported that these methods were effective in reducing patients' anxiety. However, some studies that used PEPs did not find any positive significant effects. This could be attributed to differences in the content and techniques used or to the methods. For example, Howells et al. provided information leaflets before colposcopy and Hartford et al. implemented psychological training methods through telephone contact [10,21]. It appears that PEP is more effective if it is applied in a face-to-face approach.

In general, it seems that PEP can reduce patient's anxiety by providing general information about the screening program, teaching relaxation techniques, emotional support with empathy and unconditional positive acceptance, and trying to encourage the patients in times of stress and improve their tendency to accept the importance of the procedure. It was shown with the results of this study that psychoeducation is not effective in reducing the patient's pain during the colposcopy.

Various studies have been performed on the effect of PEP on pain caused by therapeutic interventions, especially after surgery. For example, Horn et al. studied preemptive and preventive pain psychoeducation and its potential application as a multimodal perioperative pain control option [22]. Ozturk et al. confirmed the positive effects of psychoeducation on anxiety and pain in patients complaining of mastalgia [15]. Jochum et al. studied the effect of psychoeducation and physiotherapy on the reduction of chronic myofascial pain [23]. These studies showed the positive effect of psychological training on pain reduction, which contradicted the results of our study.

It seems that PEP can reduce pain and the need for analgesics after surgery by raising awareness, reducing anxiety, changing attitudes toward pain, and providing information about expected pain and how to deal with it [22,24,25].

The inconsistency of the results of the present study with the previous research may be due to differences in the nature, and severity of pain, the acuity and chronicity, and the nature of disease. Since women who are candidates for colposcopy do not experience pain before colposcopy and the procedure itself does not cause severe pain, this pain is not clinically notable.

CONCLUSION

Based on the results, it seems that PEP is a useful, effective, and economic method that can reduce anxiety. Also, considering the psychological needs of women and the positive effect of this intervention on women's psychological condition, it is recommended that PEP interventions be added to medical and nursing education curricula, and it is also recommended to study the effect of this intervention on other aspects of women's mental health as well as other medical interventions.

Conflicts of interest and sources of funding

The authors do not declare a conflict of interest. This study was extracted from the general medical thesis of Kashan University of Medical Sciences. This article was funded and supported by the Deputy of Research, Kashan University of Medical Sciences, Grant No: 2806.

Authors' contribution

Conceptualization and supervision: Z.V and M.A; Data collection, M.J; Data analysis: F.S.A; Writing-original draft and Writing-review & editing: M.A and F.S. A; Final approval: All authors.

Ethics approval and consent to participate

This study was registered in the Iranian Registry for Clinical Trials (IRCT) with registration code 20130721014086N12.

Acknowledgments

We would like to thank the staff of the Women's Clinic of KAUMS, and the Deputy for Research and Technology of Kashan University of Medical Sciences, for their cooperation in conducting this study.

Abstract: *Background: Healthcare providers should care for everyone without discrimination based on gender, race, religion, ethnic background, and social and economic status. Therefore, considering the importance of ethical challenges in war, this study was conducted with the aim of investigating the ethical challenges of healthcare providers in war. Method: This integrative review study was conducted in the field of ethical challenges for healthcare providers in war. Using the keywords of ethics, challenge, war, and healthcare providers that were selected based on the words of the medical subject heading (Mesh); a targeted search was conducted under the title and abstract in Google Scholar, ProQuest, SID, Web of Science, PubMed, Elsevier, and Scopus from 2000 to November 2022 and in Persian and English languages. Findings: twelve articles of 1160 were reviewed. Findings showed that healthcare providers face ethical challenges in war, including discrimination in care, unprofessional work, cultural and gender care, ethics versus security, and ethical decisions. Conclusion: Recognizing ethical challenges and providing solutions helps to provide better care and save people's lives in war. Developing programs for the preparation of health service providers, using existing experiences, emphasizing religious and humanitarian teachings, and holding periodical missions, can prepare health service providers to face these ethical challenges.*

Keywords: *challenge, ethics, morality, war, healthcare providers*

INTRODUCTION

Patient care is based on ethics [1]. In addition, compliance with the principles of professional ethics is the right of recipients of health care [2]. Crises and natural disasters are exceptional situations that make healthcare providers face many ethical challenges along the way in providing care. The professional competence of health care providers depends on adherence to the principles of professional ethics. The issue of professional ethics becomes more important, especially in difficult situations and natural disasters. On the other hand, healthcare providers, who play the main role in disaster-based relief, when they are in critical situations, face many ethical challenges [3].

Ethical performance is one of the main components in providing comprehensive and high-quality care to patients, especially in critical situations [4]. It is necessary to pay attention to the issues of professional ethics, especially in times of crisis and natural disasters, because the provision of health care in a normal situation is different from a crisis, and it causes more ethical responsibilities [5].

Wartime care is an undeniable reality in current clinical practice. Being at war situation can happen to anyone, including care providers [6]. The review and comparison of various studies regarding the experiences of healthcare workers during the war show that most of the results of these studies indicate the continuous and self-sacrificing efforts of this group in providing medical services to the wounded and injured despite the enormous pain and suffering they endure [7]. Health service providers are obliged to take care of everyone without discrimination based on gender, sexual orientation, race, religion, ethnic background, and social and economic status. This standard is true in all the countries of the world and is expressed in rituals such as the code of ethics for nurses of the International Council of Nurses [8].

According to the declaration of the World Medical Association (WMA) published in 2012, medical ethics in wartime is the same as medical ethics in peacetime, and adherence to medical ethics standards in wartime and peacetime is essential [9]. Since healthcare personnel are also present in the war zone along with military personnel, and they work in different environments such as battlefield field hospitals and air transport and evacuation, they face very important ethical challenges [10]. Studies show that healthcare providers suffer many problems and hardships during the war, including moral challenges, (for example: discrimination in care, care of enemies, and safety) which have many positive and negative effects on them [11]. During the Iran-Iraq war, healthcare providers faced ethical dilemmas caused by challenges such as insufficient personnel and facilities to deal with critically ill patients when referring large numbers of wounded soldiers and insufficient information on the care of victims of chemical attacks [12]. The experience of moral challenges in the war zones of Iraq made health service providers face psychological distress [13].

The Syrian civil war has created an environment of violence and instability in which humanitarian health workers have repeatedly faced ethical challenges that have resulted in ongoing threats to personal safety and lasting psychological trauma. Challenges include disruption of services during an attack, relocation or reconstruction of health facilities, limited access to resources, equipment, or medical supplies, lack of qualified personnel, dealing with armed groups, working with local communities, gaining organizational support for decisions difficult, deciding to stay despite the risks, facing discrimination based on gender and experiencing distress and internal conflict [14]. In the Lebanon war in 2006, ethical challenges were experienced including the protection of employees, the continuation of normal treatment of patients, and the protection of patients by health care providers [15]. In the war in Bosnia and Serbia, the health care providers of The Netherlands, who were stationed in the conflict centers, faced ethical challenges in providing care to the wounded, such as discrimination in care and conflict with military duties [16].

There are certainly cases of terrible or tragic behavior during war that many ordinary citizens, and most military members, do not remember with pride or approval. The My Lai massacre during the US war in Vietnam, prisoner abuse at the Abu Ghraib prison in Iraq, “saturation” or “terror bombing” of German cities by Allied forces toward the end of World War II, the use of nuclear weapons against civilian targets in Japan, the killing or severe mistreatment of prisoners of war by all sides in the Atlantic and Pacific theaters during World War II. The list is not a short one. The preparation of healthcare providers to face moral challenges in unusual conditions and to use appropriate strategies during war is very important [10].

Therefore, due to the importance of ethical challenges in war zones for healthcare providers and Less attention is paid to this issue, in this study, we decided to investigate the ethical challenges of healthcare providers in war.

It should be noted that today we are facing wars in different parts of the world and healthcare providers in the context of these wars are facing many ethical challenges and our information about them is very limited. Since there is an information gap in the healthcare provider's ethical challenges in war, this study was conducted with the aim of investigating the ethical challenges of healthcare providers in war. The question of this study: What are the ethical challenges that healthcare providers face in war?

MATERIALS AND METHODS

Because the methodology of the reviewed studies was different and unsuitable for statistical analysis, an integrated review method was used. This integrated study was carried out with the help of the guidelines provided in Hanna Snyder's article [17]. An integrative review is a method that collects and synthesizes the knowledge generated through the analysis of results extracted from selected studies. This study was carried out in the following steps: Setting the research question. Sampling or selection of studies for review; Introduction of reviewed studies; Analysis of selected studies; Interpretation of results and final report [18].

The research question was: "What ethical challenges do health service providers face in war?" In this regard, the researchers searched native and international databases such as SID.ir, Iranmedex, PubMed, Web of Science, Scopus, and Google Scholar, with the keywords War, Healthcare Providers, Challenge, morality, and ethics in the years 2000 to 2022. For Iranian databases, keywords were searched in Farsi and English. In this way, related articles in this field with quantitative and qualitative approaches are extracted. Gray sources, such as unpublished results, dissertations, and articles published in sources with low credibility, were excluded due to their insufficient credibility (Table 1).

The criteria for entering the study were: relevance and continuity in the subject of study, publication of the article in Persian and English language, and the availability of the full text of the article; The criterion for selecting the article after the search was the relevance to the article context for the question from the study. At first, 1160 articles were extracted, and after evaluation by the research group based on the inclusion criteria, 12 articles were studied and analyzed by removing irrelevant and duplicate articles. Figure 1 describes the PRISMA method in extracting the target articles.

RESULTS

From 1160 articles that obtained in the first stage by searching the key words mentioned, after removing the articles not related to the subject of the study and complying with the inclusion and exclusion criteria, finally 12 articles that related to the purpose of the study examined. The findings of this study showed the ethical challenges of health service providers in war zones in terms of: Discrimination in care, Unprofessional work, Cultural and Gender care, Ethics versus Security and Ethical Decisions. A summary and complete description of the reviewed studies showed in the Table 2. This review summary includes authors, year of publication, methodology and results (Table 2).

Table 2: Final articles used in the study

DISCUSSION

The purpose of this study was to consolidate the results of studies related to the ethical challenges of healthcare providers in war. Ethical challenges of healthcare providers in war mentioned in the areas of discrimination in care, unprofessional work, cultural and gender care, ethics versus security and ethical decisions.

Discrimination in care

Discrimination, in the non-moralized sense, is ubiquitous. Discrimination is a surprisingly slippery concept, and much of the attention it has received in recent years has focused on constructing a precise definition of the term. At least in part, this may be because the concept appears to cover such a wide variety of disparate cases crossing traditional boundaries in applied ethics and political theory, from distributive justice, medical ethics, and criminal justice to multiculturalism, liberal rights, and feminism [26].

Everyone is entitled to human rights without distinction of any kind, such as nationality, race, religion, age, gender, sexual orientation, economic background, or disability. Even if humanitarian workers are trying to do things well, they usually cannot do everything that is needed. In most situations, humanitarian organizations are faced with rationing problems difficult choices about exactly who they can help and what they can do. With limited resources and typically widespread needs, organizations have to focus. To focus responsibly means finding a need that one's agency is good at meeting—this may be health, food, or protection—and maximizing their programs in some way so that as many people benefit as possible [27].

When supplies are short, who is first in line? Health service providers at war environment always faced by a lack of medical facilities due to the special conditions prevailing in war. Using these limited facilities to save the lives of many people who injured in the war environment is one of the ethical challenges of health service providers. These challenges will be more difficult when caring for enemies wounded, prisoners of war and indigenous people. In addition, the decision to save a person in a critical situation, which may be accompanied by neglecting to save sicker or dying people, is a challenging situation for health service providers [13,19, 20,22].

The evidence indicates that the health service providers faced by a series of moral dilemmas, including discrimination in providing care to patients, and due to political beliefs and culture, they tried to have less contact with the enemy wounded. In this regard, the results of Desch-Scannell and Doherty's study showed that nurses did not want to provide care to the enemy wounded. In addition, the results of Lal and Spence's study showed that due to the limitations of medical equipment, human and technical resources, nurses had to perform differently than the injured and make difficult decisions about providing care to people. Limitation of resources in providing care knew as one of the ethical challenges of health service providers in war [10,14,16,21]. The decision to save the seriously injured for whom there is no hope for a healthy life or the wounded who are at risk of death and their care in war conditions lead to a waste of limited resources is one of the ethical challenges of health service providers [8,14,21].

Discrimination is sometimes the product of what the discriminator takes to be a fundamental distinction between classes of people. For example, placing a lesser value in war on the life of an enemy than on a country's own citizens is typically premised on a belief in a basic distinction between friend and foe, or between citizens and non-citizens. When prisoners captured they should receive treatment as prisoners of war, unless they are known to have committed criminal acts on the battlefield in contravention of the laws of war. They have a right to self-defense against other combatants, unlike terrorists, and their use of deadly force against their enemy is not considered murder [28]. International laws, say they should not, for example, be tortured during questioning. Nor can they be beaten, starved or somehow medically experimented on. They cannot be used as shields between oneself and the opposing side; the understanding is that captured enemy soldiers are to be incarcerated far away from the front lines. Moreover, very basic medical and hygienic treatment is supposed to be offered: things like aspirin, soap, water, and toothbrushes [29].

Thus, caring of prisoners under torture and cooperation of healthcare providers with investigators causes many ethical challenges. Here, hard ethical problems arise when doctors, nurses, and medics are called upon to assist in interrogation or force-feed hunger-striking inmates [30]. The use of medical staff to determine the amount of torture that a person endures, the use of psychological methods to obtain information, keeping captives alive to receive information, and the use of therapeutic tools for torture are among these challenges. In these situations, emotional responses such as anger, fear, resentment, hate and prejudice are in conflict with moral requirements [24,31,32].

Unprofessional work

The quality of humanitarian action is a constant concern in humanitarian ethics. The great majority of humanitarian workers recognize that it is not enough simply to try to help people. One must help them professionally and well. As a result, there has always been a considerable effort put into standard-setting, professional guidelines, training, and competence [27]. One of the ethical challenges of health service providers in the war is the employment of people in non-specialist positions in the conditions of shortage of specialist personnel. Although in many cases this issue has caused more growth and training in health service providers, it faces people with ethical challenges in providing care that they do not have enough skills. For example, health service providers were faced with the challenge of caring for children injured in war that they may harm them during care [19,20, 24]. Furthermore, healthcare providers realized that they have not fully trained to treat a wide range of injured patients, including severe traumas, extensive bleeding and critical care, health problems, care of infants, women, children, and the elderly [13]. Because of staff shortages, participants emphasized the difficulty of taking on new roles for which they not trained. They feel forced to play multiple roles or provide care beyond their skill level. In addition, volunteers who came to hospitals without educational qualifications will cause ethical challenges [14].

Cultural considerations

Today, official declarations abound avowing the indispensability of gender inclusiveness and diversity for military effectiveness in the twenty-first-century operating environment. Today's "militaries rely more and more on women and members of visible minority and Aboriginal groups to fill their ranks, rendering the recruitment, retention, and optimum employment of these members important to the success of the organization from the perspectives of both operations and public accountability. In some units and services, women and members of nonwhite ethnic, non-Judeo-Christian religious, or non-heterosexual minorities have been integrated effectively. However, equal opportunity and diversity policies have not been uniformly successful. Oftentimes, our inability to understand other's culture is a direct cause of needless strife and deprivation. The past decade of armed conflict speaks emphatically to the increased pain and suffering that follow from our violating the cultural norms of countries that have the misfortune of playing host to militaries [30].

Taking care of an injured patient of the opposite gender

The presence of women in military teams as well as their use as health service providers in the war environment is facing issues such as moral challenges. Providing security, meeting the needs of women, maintaining privacy, preventing sexual assaults, and providing health care to injured women can be among the ethical challenges of health service providers in war. Furthermore, not paying attention to local culture in the place of war, especially in relation to women, can cause health service providers to face ethical challenges [23].

Difference in values

Another ethical dilemma in the field of cultural difference between nurses and injured people was the difference in values, especially regarding gender. Some patients believed that women's bodies should not be exposed to men, even if that man is a health service provider [10,13]. Cultural differences identified between health care providers and patients lead to ethical dilemmas. Findings indicated that health care providers had difficulty confronting cultural norms that conflicted with care delivery. Gender issues can lead to differences in care and expectations regarding female patients. Based on the male dominant role, men were the main decision-makers and could dictate the provision or care of female members or children of the family. Cultural customs in terms of social, political and economic factors are effective on ethical challenges when providing care [8,13,24]. Furthermore, women's health service providers face ethical dilemmas while taking care of men who avoid contacts with women [14].

Ethics versus security

One area of humanitarian ethics that is often uppermost in the minds of humanitarian workers in armed conflict is the level of risk they are prepared to accept for themselves and their teams as they try to help others at risk. Humanitarian workers like soldiers, policemen, and firefighters may genuinely expect to suffer and die in pursuit of their duty. Humanitarian workers have often died while doing their jobs—most usually from infectious diseases or traffic accidents. Armed actors of various kinds also deliberately kill them as humanitarian workers. The ethics of personal risk in humanitarian action is not discussed publicly very much in order to maintain the moral and legal taboo on killing humanitarian workers. However, in reality, many humanitarian workers decide to put their lives at risk every day. To do so responsibly means balancing risks against results how important is it to deliver this convoy today? It also means working with a strong duty of care towards one's staff and with their full and informed consent when it comes to engaging in risky operations [27].

In addition, one of the ethical dilemmas of healthcare providers at war environment is maintaining the safety of employees and recognizing when to leave the war environment. Sometimes health care providers have to make a difficult choice between saving someone's life and their own safety and health, because laws regarding the immunity of health care providers in war not always respected. When the order to leave an environment announced, healthcare providers may face with a lack of facilities to evacuate the injured. In this situation, they should act between staying and protecting the injured or leaving the situation according to the order [14,25].

Sometimes leaving a wounded person alone for a few minutes, for example, during the warning of an imminent attack, may endanger his life. In such a situation, the decision to go in to the shelter or stay with the injured will create a significant challenge [15,16]. Facing organizational needs in opposition to the needs of the injured, such as applying pressure from the commanders to provide service to an injured person, or releasing some of the injured, or transferring the injured who are not ready to be transferred, puts healthcare providers in a situation of ethical challenges [21].

The intervention or pressure of armed groups to leave the triage process and accepted clinical practice was one of the ethical challenges of the treatment staff. This included verbal threats, harassment, humiliation, acts of violence, and requests for preferential treatment for some patients, such as members of armed groups or their family members. Obligation to comply with laws contrary to medical requirements, requests for participation in decision-making, and intervention in medical affairs, under threat from the military, are among the ethical challenges of health service providers in war [14].

Ethical decisions

“Working to enhance national security,” writes the BMA, “may not always be compatible with the fundamental tenets of medical ethics.” This is one of the central dilemmas of military medical ethics: To whom do medical practitioners—doctors, nurses, and medics—owe their loyalty? Are they caregivers or soldiers first? Here is a dual-loyalty dilemma in the most quotidian terms: the patient’s interests or those of the military? The mission of the Army Medical Department is to conserve the fighting strength. Combat health support maximizes the system’s ability to maintain presence with the supported soldier, to return injured, sick, and wounded soldiers to duty, and to clear the battlefield of soldiers who cannot return to duty [30].

The most controversial issue was that military medical ethics based more on the expediency of returning soldiers to battle than treating the wounded, meaning that the priority was returning soldiers to duty rather than providing care to the seriously wounded. The moral challenge for many was about returning to war, including soldiers who wanted to return to combating but were judged unsuitable and those who did not want to return but were deemed fit. Health service providers considered this as a great moral responsibility both towards the patients and towards the mission [21,24].

The most troubling ethical issues cited related to conflict with physicians in treatment decisions, working with incompetent or unprofessional colleagues, and staffing patterns. Among the resources that helped nurses in dealing with ethical issues, role models, staff meetings, and physician, supervisor, and peer consultations more used. However, nurses also used professional sources (journal articles and books) and personal sources (church) [24].

CONCLUSION

The findings from this study showed that health service providers face many ethical challenges in providing health services while in war zones. Understanding these challenges in order to provide solutions to face them helps to provide better health services and save people's lives in the battle scene. One of the applications of this study for health service providers is that it informs them about the ethical challenges in the battlefield so that they can make the right decision in the event of war. Decision-making training in critical situations seems essential for healthcare providers. Healthcare providers must have adequate military training to protect themselves and the injured. Developing programs for the preparation of health service providers, using existing experiences, emphasizing religious and humanitarian teachings, and holding training maneuvers can be effective in preparing them to face these ethical challenges. Holding classes to be acquainted with the local culture of the war zone and the values governing the society before deployment is effective in reducing moral problems. Managers should consider providing mental health services to people who provided care in war zones and faced moral challenges.

Conflicts of interest and sources of funding

The authors declare that there is no conflict of interest in the present study.

Authors' contribution

GDM conceived of the presented idea. KhM, VZ contributed to documentation on the topic of interest, work conception and revised the manuscript. GDM, KhM, VZ performed the final revision of the manuscript. All authors discussed the results and contributed to the final manuscript. KhM and VZ gave final approval. All authors have read and agreed to the published version of the manuscript. PH, HS, GDM had equal contributions.

Ethical considerations

In the present study, all ethical considerations, including the condition of trust and honesty, have been taken into consideration. The present study was written in line with the results of the doctoral dissertation in nursing approved by Baqiyatullah University of Medical Sciences with the ethics code IR.MBSU.REC.13990442.

Abstract: *Nutritional interventions in the field of psychiatry have been explored more intensively in the last two decades, but definitive conclusions based on the retrieved data in the literature about the efficacy of this therapeutic approach are difficult to formulate. This observation has multiple explanations, e.g., these therapeutic interventions are very heterogenous, cohort studies usually enroll different psychiatric populations or healthy subjects with minor psychiatric symptoms, nutritional supplements or special diets are commonly recommended as add-ons to the pharmacological interventions (thus making it difficult to differentiate the impact of each therapy on the outcomes), placebo-controlled randomized studies are still very few, etc. Therefore, a narrative review focused on the main challenges reported during the research in the field of nutritional psychiatry (NP) may be useful for clinicians interested in strategies to augment the efficacy of pharmacological treatments or to find new solutions with low risk of adverse events in patients with organic comorbidities or multiple concomitant medications. Data about the efficacy and tolerability of nutritional interventions explored for psychiatric disorders were searched in four electronic databases (PubMed, Cochrane, Clarivate/Web of Science, and EMBASE). Omega-3 polyunsaturated fatty acids supplementation, healthy diet interventions, folate and vitamin B12, S-adenosyl-L-methionine, N-acetyl cysteine, vitamin B1 and B6, vitamin D, minerals, psychobiotics, inositol, and herbal products were the main interventions identified, and their demonstrated efficacy was quite heterogenous, while their tolerability and safety were good. Therefore, NP is a domain of research that may benefit from more good-quality and longer-duration trials, in order to verify the effectiveness of such augmentation strategies to the already validated treatments.*

Keywords: *prebiotics, probiotics, synbiotics, vitamin D, folate, B vitamins, S-adenosyl-L-methionine, N-acetyl-cysteine, inositol, micronutrients*

INTRODUCTION

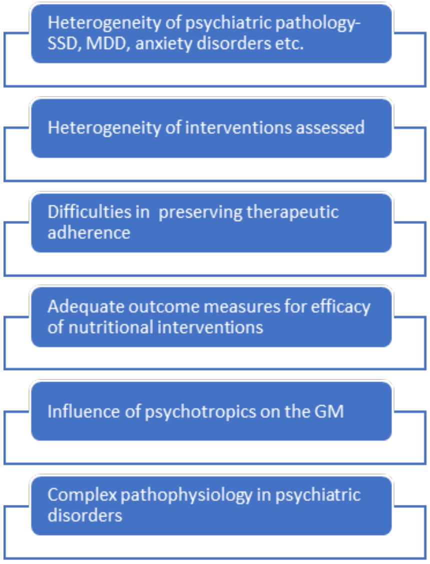
Nutritional psychiatry (NP) explores the impact of nutrient-based interventions on clinical symptoms and behavioral models of mental disorders. The number of published research in this field has continually increased during the past decades [1]. Dietary recommendations and the use of nutraceutical supplements sparked interest for psychiatrists in the management of psychiatric disorders or in the prophylactic strategies targeting the same type of disorders [1]. Nutrition has been considered able to modulate different pathophysiological mechanisms of psychiatric disorders, especially inflammation, oxidative stress, the structure of the gut microbiome, epigenetic influences, and neuroplasticity [2]. Associations between variables related to diet quality and mental health have been supported by epidemiological research, and they do not seem influenced significantly by lifestyle characteristics, demographic factors, or reverse causality [2]. There is accumulating evidence supporting the relationship between diet quality and/or feeding imbalances, on one side, and mental health, on the other [3]. Such evidence already exists for other medical specialties, such as endocrinology, cardiology, and gastroenterology [3]. Nutrient-based supplements and augmenting strategies could be of major interest to psychiatry, if proven efficient and well tolerated, because of their lack of significant pharmacokinetic and pharmacodynamic interactions with the drugs, and due to their more socially-accepted, non-stigmatizing, image as therapeutic interventions in patients with mental disorders.

The founding in the year 2013 of the International Society for Nutritional Psychiatry Research (ISNPR) reflects the importance gained by this domain in the last decade [4]. According to a position statement of this institution, diet is part of an integrative psychiatric model, and evidence-based nutraceuticals should be considered elements of case management in psychiatry [4]. The education of both clinicians and patients about evidence-based nutrition or nutraceuticals is also a key element of the ISNPR position statement [4].

Another domain of intensive exploration for nutritional psychiatry is represented by the connection between gut microbiota (GM) and the pathogenesis of mental disorders. This aspect was explored through the lens of the bidirectional signaling that was observed between the intestinal flora and the brain functioning, i.e., the microbiome-gut-axis [5]. The possibility of changing the composition of GM through probiotics, prebiotics, synbiotics, or fecal material transplantation (FMT) was considered important as an approach to psychiatric disorders [6,7]. Also, the impact of early-life nutrition and maternal diet has been investigated in connection with the onset of psychiatric disorders in offspring [1].

The results of studies investigating the efficacy of nutraceuticals in the treatment of psychiatric disorders are still far from being convincing [1]. Heterogeneity, residual confounding, measurement errors, and difficulties in quantifying and ensuring adherence to a certain diet have been considered challenges for experimental research in NP [8]. A high rate of placebo effect could be one of the factors that mitigate the difference between study groups and hinder the development of nutraceutical-oriented therapies in psychiatry [1]. Therefore, methodological aspects should be considered when interpreting the results of such trials, and the use of biomarkers, e.g., specific nutrient deficiencies, allelic variants, and metabolomic variables, should be encouraged [1]. Also, taking into consideration individual dietary patterns and nutrient necessities is important when constructing a therapeutic strategy for patients with mental disorders from the perspective of NP [1]. However, the effects of nutraceuticals are also actively investigated in different categories of psychiatric disorders and advances have been recorded in the field of mood-modifying and cognitive-improving agents in clinical populations and healthy individuals [9]. Systemic and central vascular function, inflammation, metabolism, and neuroprotection may explain the positive impact of nutraceuticals [9]. A synthesis of the methodological difficulties in finding answers to the main questions in NP is represented in Figure 1.

Figure 1: Challenges identified in the research of nutritional interventions in patients with psychiatric disorders *(SSD= schizophrenia spectrum disorders, MDD= major depressive disorder, GM= gut microbiota)*



Heterogeneity of psychiatric pathology- SSD, MDD, anxiety disorders etc.
Heterogeneity of interventions assessed
Difficulties in preserving therapeutic adherence
Adequate outcome measures for efficacy of nutritional interventions
Influence of psychotropics on the GM
Complex pathophysiology in psychiatric disorders

Psychotropics may exert different effects on the GM, thus influencing the gut-brain axis [21]. Antipsychotics have been associated with anti-commensal activity, which is difficult to explain since these agents are targeting monoaminergic neurotransmission in the central nervous system (CNS) [21]. According to a complex study that observed the influence of various non-antibiotic drugs on the growth of 40 representative bacterial isolates, which can be found in the human GM, almost all antipsychotic categories present anti-commensal activity [21]. There are suppositions that direct bacterial inhibition of antipsychotics might not be an adverse event, but a potential mechanism of action attributed to these agents [21]. However, the negative effects of this antimicrobial activity have been reported, although the significance of this effect was not yet clearly demonstrated. For example, an alteration of GM by antipsychotics may result in body weight gain and metabolic dysfunctions [22].

Antidepressants, like monoamine oxidase inhibitors (MAOIs), serotonin selective reuptake inhibitors (SSRIs) and tricyclic antidepressants also have antimicrobial properties by different mechanisms, e.g., inhibition of DNA replication, blocking of the bacterial efflux pumps, etc. [23,24]. Dysbiosis induced by this type of pharmacological agents has been considered a possible contributor to the effectiveness but also to the treatment resistance in patients with major depressive disorder (MDD) [23].

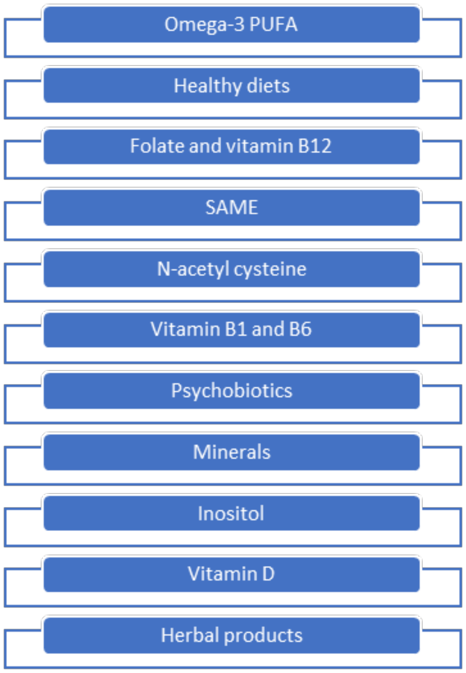
OBJECTIVE AND METHODOLOGY

Because the methodology of the reviewed studies was different and unsuitable for statistical analysis, an integrated review method was used. This integrated study was carried out with the help of the guidelines provided in Hanna Snyder's article [17]. An integrative review is a method that collects and synthesizes the knowledge generated through the analysis of results extracted from selected studies. This study was carried out in the following steps: Setting the research question. Sampling or selection of studies for review; Introduction of reviewed studies; Analysis of selected studies; Interpretation of results and final report [18].

SPECIFIC INTERVENTIONS IN NUTRITIONAL PSYCHIATRY

Data supporting the influence of nutrition, as a category of interventions, on mental health are derived from meta-analyses and systematic reviews, based on randomized controlled trials and cohort studies [25]. The main nutritional interventions found during the literature review are represented in Figure 2.

Figure 2: Main nutritional interventions explored for the management of psychiatric disorders *(PUFA= polyunsaturated fatty acids, SAME= S-adenosyl L-methionine)*



For example, a meta-review of the meta-analyses focused on nutritional interventions in the field of psychiatry (N=10951 individuals) concluded that the strongest evidence supports the use of PUFAs, especially eicosapentaenoic acid (EPA), as an adjunctive treatment for MDD, and the therapeutic potential of these interventions for ADHD; folate supplements, and especially high-dose methyl folate regimens, were associated with positive results in MDD; emergent evidence for N-acetylcysteine as an adjunctive for mood disorders and schizophrenia were reported [26]. All nutritional interventions assessed had good safety profiles, without evidence of serious adverse effects or contraindications in psychiatric disorders [26]. Another review (n=69 trials) reported the statistically significant or clinically important changes observed in the majority of the research conducted (n=48 trials) when nutritional interventions were used as supplementation for psychiatric disorders; however, the heterogeneity of the psychiatric diagnoses, clinical outcomes, and treatments assessed preclude the extraction of definitive conclusions [27].

Omega-3 polyunsaturated fatty acids supplementation

EPA and docosahexaenoic acid (DHA) are the two ω-3 PUFAs explored in the treatment of psychiatric disorders based on their anti-inflammatory role, involvement in preserving neurons' stability, and possible importance for the proper functioning of neurotransmission [28]. The American Psychiatric Association practice guideline for depression recommends ω-3 PUFAs as adjunctive therapy in patients diagnosed with MDD [29].

In a placebo-controlled study, 2.4 g/day ω-3 PUFAs were added to venlafaxine in a group of 72 patients presenting their first episode of depression [30]. After 12 weeks, both groups (active and placebo) had improvements in their clinical status vs. baseline, but the rate of responders for anxiety symptoms was significantly higher in patients who received PUFA at week 4 [30]. These results support a possible faster response in patients who received venlafaxine + PUFA regarding their associated anxiety symptoms, although the final scores did not differentiate between the two groups [30]. Also, childhood trauma and lack of social support have been associated with poor prognosis in patients with first episodes of depression in this study [30].

A double-blind, placebo-controlled trial evaluated the effects of ω-3 PUFAs (3.4 g/day) as monotherapy vs. placebo in pregnant women (N=36) with MDD during eight weeks [31]. Patients in the active intervention group had significantly lower HAMD (Hamilton Depression Rating Scale) scores at week 6 and at the endpoint, higher response and remission rates [31]. Also, the changes in the secondary outcome measures (EPDS- Edinburgh Postnatal Depression Scale and BDI- Beck Depression Inventory) supported the significant efficacy of PUFAs vs. placebo [31]. The tolerability of PUFAs was good, without adverse effects reported by either mothers or newborns [31].

A meta-analysis (n=19 trials, N=2240 participants) supported the existence of a beneficial effect of ω-3 PUFAs vs. control interventions over anxiety symptoms [32]. The subgroup analyses showed that patients with well-defined psychiatric conditions responded better to adding ω-3 PUFAs than individuals without clinical diagnoses [32]. The anxiolytic effect of ω-3 PUFAs was superior to controls in subgroups with a higher dosage (≥2 g/day) vs. a lower-dose regimen [32].

Epidemiological studies reported a correlation between reduced levels of ω-3 PUFAs or low intake of fish products and the increased risk for age-related cognitive decline or AD [33]. Also, increased dietary consumption or blood levels of DHA are protective against AD and other dementia in epidemiological studies, with a possible negative interference from the apoE4 genotype [33].

Possible mechanisms explaining the protective effects of DHA against cognitive decline and AD are the following: some of its metabolites have neuroprotective effects, there is a decrease in the production of arachidonic acid metabolites, the transduction for trophic factors is increased, and the inhibition of signal transduction pathways induced by β-amyloid is more intense [33].

The addition of ω-3 PUFAs in patients with ADHD has been explored starting from the potential benefits of these agents on oxidative stress (which can be increased in this population), inflammation (by competitive inhibition of the ω-6 PUFAs, which are pro-inflammatory), and increasing levels of dopamine and serotonin neurotransmission [34]. Meta-analyses report small to insignificant effect sizes on ADHD behavioral symptoms of ω-3 PUFAs when added to ongoing medication [35-38]. The overall tolerability of ω-3 PUFAs was good, and no severe adverse were reported in these meta-analyses [35-38]. Dyspepsia and transient nosebleeds have been the most frequently reported adverse events [34-38]. In patients with ADHD and developmental disorders or other comorbidities, the add-on of ω-3 PUFAs may lead to superior results when compared to other groups [35].

Schizophrenia has been associated with alterations in lipid metabolism and antipsychotic treatment supplementation with ω-3 PUFAs has been explored as a potential way to improve these patients' prognosis [39]. A recent systematic review (n=26 clinical studies) found that the results of ω-3 PUFAs supplementation may significantly improve positive and negative symptoms during the prodromal phase, ameliorates the negative symptoms during the first episode of psychosis (FEP), and has a favorable, although partial, effect in patients with chronic schizophrenia [39]. The effects of ω-3 PUFAs in this population are modulated by demographic variables (e.g., age), clinical variables (e.g., duration of untreated psychosis), and the status of antioxidant processes in individuals with psychosis [39].

Healthy diet interventions

According to a review dedicated to dietary interventions for the prevention of depression, five recommendations are supported by evidence: "traditional" diets (e.g., Mediterranean, Norwegian, or Japanese diet); increased consumption of fruits, vegetables, legumes, wholegrain cereals, nuts, and seeds; high use of foods rich in ω-3 PUFAs; replacement of unhealthy foods with wholesome, nutritious foods; reduction of processed foods, " fast-foods", sweets, etc. [40]. Low-carbohydrate high-fat diets may be useful in improving the outcome of anxiety disorders and ADHD [28,41]. This type of ketogenic diet has anti-inflammatory effects due to the lower production of reactive oxygen species and free radicals [28].

A multicenter, randomized study focused on preventing cardiovascular disease evaluated the effects of the Mediterranean diet supplemented with nuts in community-dwelling men (age 55-80 years) and women (age 60-80 years) at high risk of cardiovascular disease vs. the control group (low-fat diet) [42]. A number of 224 new cases of depression were identified at follow-up (after three years), and an inverse association with depression was reported for patients with the Mediterranean diet vs. the control group, but this was not significant [42]. When only patients with type 2 diabetes mellitus were included in the analysis, the magnitude of the effect determined by the dietary intervention did reach statistical significance [42].

Dietary interventions as adjuvants to the treatment of moderate to severe MDD were evaluated by comparison with social support group, in a single-blind, randomized controlled trial for 12 weeks, with 67 participants [43]. The nutritional intervention consisted of personalized dietary advice and counseling conducted by a clinical dietician who respected the "ModiMedDiet" program [43]. Whole grains, vegetables, fruit, legumes, low-fat and unsweetened dairy foods, raw and unsalted nuts, fish, lean red meats, chicken, eggs, and olive oil were the core ingredients of this dietary intervention (18% protein, 40% fat 37% carbohydrates, 2% alcohol, and fiber/other 3% of the total energy) [43]. After 12 weeks, the results of MADRS supported the superiority of the active intervention vs. social support (control) at a significant level [43]. Remission (MADRS score <10) was reported in 32.2% of the active intervention group vs. only 8% of the control group, a statistically significant difference [43].

In a prospective, randomized trial, adults (N=152) who had depressive symptoms received MedDiet cooking workshops and food hampers for 12 weeks, plus fish oil supplements for six months vs. participation in social groups for three months [44]. The MedDiet group used more vegetables, fruit, nuts, legumes, whole grains, and vegetable diversity, less unhealthy snacks and red meat/chicken [44]. At the endpoint, the MedDiet group presented a lower severity of depression and improved quality of life scores; at six months improved diet and mental health were sustained in this group [44]. Reduced depression correlated with increased MedDiet score, use of nuts and vegetable diversity [44].

The relationship between adherence to the Mediterranean dietary pattern and the prevalence of psychological disorders in adults was investigated in a cross-sectional study (N=3172 participants), using the Hospital Anxiety and Depression Scale (HADS) and General Health Questionnaire (GHQ) as outcome measures for mental health [45]. A high intake of fruits and vegetables was associated with a lower risk of depression, anxiety, and psychological stress [45]. On the contrary, a high intake of grains was more frequently detected in individuals who presented depression, anxiety, and psychological distress [45].

A cross-sectional study (N=5371 individuals from the general population) reported a significant correlation between a healthy diet (vegetables, salads, fruits, rice, pasta, cereals, fish, wine, non-processed meats) quality score (based on Food Frequency Questionnaire, FFQ) and a lower risk for depression and anxiety in women and a similarly lower risk for depression in men (evaluated in HADS) [46]. A traditional Norwegian diet (fish, shellfish, potatoes, fruits, vegetables, butter, margarine, milk and yogurt, bread, pasta, rice, meat spreads, legumes, and eggs) was associated with a reduced risk of depression in women and anxiety in men, while a western-type diet (meat, liver, processed meats, pizza, salty snacks, chocolates, sugar and sweets, soft drinks, margarine, mayonnaise, French fries, beer, coffee, cake, and ice cream) correlated with higher anxiety in men and women [46].

Also, the “healthy Japanese” diet (high intake of vegetables, mushrooms, seaweed, soybean products, potatoes, fish, shellfish and fruits) was inversely correlated with depressive symptoms severity during an exposure-response association study 47]. It is hypothesized that this type of diet exerts its beneficial effect (as opposed to “sweets-fat” and “ seafood-alcohol” patterns) through an anti-inflammatory diathesis, which might act as a factor for decreasing the risk for mood and anxiety disorders [47].

Folate and vitamin B12

Preclinic evidence to support the direct influence of folate and cobalamin on CNS functioning has been gathered, and the relationship between the deficits of these substances and the onset or worsening of different psychiatric disorders has also been explored with convincing results [48]. Folate deficiency has been associated with neurocognitive disorders and MDD, while the cobalamin deficit can be connected to psychosis [48]. Both folate and vitamin B12 are essential for the process of homocysteine methylation and for the synthesis of S-adenosyl-L-methionine (SAMe) [49]. A defect in the methylation process has been hypothesized as the key to the pathophysiological basis of many neuropsychiatric disorders [49]. The toxic effects of homocysteine can also be part of the negative effects of folate and vitamin B12 deficiency [49]. The causal relationship is, however, still unclear, and multiple variables are modulating the effects of vitamin B12 deficiency [48]. Also, it is important to note that normal hematological indices do not automatically exclude vitamin deficiencies [48].

According to a meta-analysis (n=43 studies) that explored the relationship between levels of folate and depression, a small but statistically significant effect size was found (low levels of folate correlated with a higher risk of depression) [50]. This meta-analysis had a high heterogeneity (over 84%), which could not be explained by the folate measurement methods or study population [50]. Regarding the relationship between cognition and vitamin B12 deficiency, the context of its investigation is more complex. According to a meta-analysis (n=21 observational studies, adults ≥45 years old), higher levels of vitamin B12 and folate were associated with better cognitive functioning in cross-sectional research, but not in prospective studies [51]. Yet, another meta-analysis (n=95 studies, N=46175 participants) concluded that B vitamins have a positive impact on cognitive functioning (assessed by Mini-Mental State Examination, MMSE) [52]. B vitamins can slow cognitive decline in prospective studies, especially on long-term administration (over 12 months) [52]. In individuals without dementia, B vitamin supplementation slowed cognitive decline vs. placebo, but this effect was not observed in patients with neurocognitive disorders [52]. Lower folate levels, but not lower B12 or B6 vitamins level, and higher homocysteine levels were significantly correlated with a higher risk of dementia [52]. Also, a higher intake of dietary folate, but not of B12 or B6, was associated with a lower risk for dementia in the old age population [52].

Adjunctive folate for psychiatric disorders can be an efficient intervention, but the results of good-quality clinical trials differ in terms of results. According to a systematic review (n=14 studies), adjunctive folate did not improve the total psychopathology, positive, negative, or general symptoms more than placebo in patients with schizophrenia, but it was superior in patients with bipolar or unipolar depression, in terms of decreasing the severity of the depressive symptoms [53]. Also, in patients with bipolar disorder, adding folate to the conventional treatment of acute mania had a favorable impact in terms of efficacy [53]. The overall tolerability of folate was good, in terms of discontinuation due to adverse events [53].

Another review (n=23 studies) concluded that oral levomefolic acid or 5-methyl folate was the most frequent nutritional factor associated with improvements in clinical status in patients with psychiatric disorders, mainly MDD, including postpartum and post-menopausal depression, schizophrenia, autism spectrum disorders (ASD), ADHD, and bipolar disorder, with a variable magnitude of effect [54]. The tolerability of folate supplements was reported as good [54].

Vitamin B1 and B6

Thiamine (vitamin B1) is a cofactor for many enzymes involved in energy metabolism, biosynthesis of nucleic acids, and anti-oxidative stress protective mechanisms [55]. Because of the importance this vitamin has in ATP mitochondrial production, thiamine deficiency can be associated with neurologic, cardiovascular, and psychiatric dysfunctions manifested as confusion, memory deficits, sleep problems, encephalopathy, ataxia, or congestive heart failure, but it can also lead to death, in severe cases [55]. Wernicke encephalopathy is the result of an acute thiamine deficiency and usually appears as a consequence of alcohol abuse [55]. This disease has as its main clinical features ataxia, loss of coordination, memory deficits, confusion, and ophthalmoplegia, and it could result in death in 17% of the cases, in the absence of appropriate treatment [55]. Korsakoff's syndrome may result from a thiamine deficit and has a chronic evolution, with short-term memory deficiencies and hallucinations [55]. Also, depression in adults has been associated with low levels of thiamine, and more severe mood symptoms have been correlated with lower levels of thiamine in the erythrocytes [56].

Pyridoxine (vitamin B6) is part of the synthesis processes of certain neurotransmitters and it has been invoked as a potential contributor to the pathogenesis of AD, ASD, ADHD, anxiety disorders, depression, and psychosis [57]. Patients with mood disorders had low pyridoxine and riboflavin levels in a study with 172 participants [58].

A cross-sectional study evaluated the correlation between dietary intake of vitamin B6 and the risk of depression and anxiety in 3362 adults [59]. The supplementation of the ongoing antipsychotic treatment with vitamin B6 (up to 400 mg/day) in a 9-week, double-blind, placebo-controlled, cross-over study in 15 patients with SSD did not lead to differences between active and placebo groups, according to the Positive and Negative Syndrome Scale (PANSS) [57]. However, a subgroup of patients with schizophrenia and comorbid minor depression may benefit from pyridoxine adjuvant treatment, as reported during an open-label study (N=9 patients) [60].

Vitamin D

A favorable impact of vitamin D was suggested for the preservation of mental health because this substance may interfere with complex homeostatic, trophic, and immunomodulatory mechanisms that can modulate different processes in the CNS [61]. A systematic review of the studies (n=14) which included various doses of vitamin D supplementation explored the effects of this intervention on mental status in healthy adults [62]. The majority of studies do not support a favorable impact of vitamin D supplementation, but data on depression outcomes were conflicting [62]. Vitamin D combined with physical activity could be more efficient than vitamin D in these patients, and there is evidence to recommend vitamin D from food sources instead of vitamin supplementation [62].

Another review (n=61 articles) concluded that a relationship between vitamin D and depression is possible, but its causality is uncertain [61]. A more important effect of this supplementation was observed in patients with MDD and vitamin D deficiency [61]. Serum vitamin D levels inversely correlate with the clinical severity of depression, but the results of clinical trials are not consistent enough to recommend a regular supplementation of the diet with this vitamin in patients with MDD [61]. A meta-analysis demonstrated that vitamin D supplements administered in patients with psychiatric disorders (N=9 trials) can reduce the BDI scores, improves the quality of sleep on Pittsburgh Sleep Quality Index (PSQI), and increase the glutathione and total antioxidant capacity while decreasing the level of C-reactive protein [63].

Neonatal vitamin D deficiency is correlated with an increased risk of schizophrenia, and preclinical studies support the alteration of brain development by vitamin D deficiency leading to subtle neurochemical and cognitive changes that may represent vulnerability factors for schizophrenia [64]. Also, patients with schizophrenia or even first-episode of psychosis may have an increased risk of vitamin D deficiency vs. healthy controls [64].

A cohort study (N=152 participants with various psychiatric diagnostics) assessed the correlation between the Brief Psychiatric Rating Scale (BPRS) and the plasma levels of 25-HO-vitamin D and parathyroid hormone (PTH), as well as the calcium serum levels [65].

The study concluded that a negative relationship may exist between serum levels of 25-OH-vitamin D and BPRS total and items scores, and inpatients had lower PTH and 25-OH-vitamin D levels [65]. This trend toward vitamin D deficiency in hospitalized patients was not dependent on the specific diagnosis or diagnosis category [65].

S-adenosyl-L-methionine

SAMe is a compound with essential roles in multiple biochemical reactions, which impact the production of molecules involved in the regulation of monoaminergic transmission [66]. Therefore, SAMe can modulate the pathophysiological mechanisms of MDD, and there are studies suggesting the antidepressant efficacy of this compound [66]. SAMe in monotherapy has been proven superior to placebo and tricyclic antidepressants, while other studies demonstrated its efficacy in patients with SSRIs- and serotonin and norepinephrine reuptake inhibitors (SNRIs)-non-responsive MDD [66]. These data are derived from open-label trials and placebo-controlled randomized trials, which investigated the effects of oral and parenteral SAMe, in doses varying from 200 mg/day (i.v.) to 1600 mg/day (p.o), and durations of treatment between 2 and 21 weeks [66-69].

According to a meta-analysis (n=13 uncontrolled trials and 25 controlled studies), the response to SAMe was superior to the placebo, and the global effect size ranged between 17% and 38% [70]. The antidepressant effect was comparable to that of tricyclic antidepressants in this meta-analysis [70].

The results of a Cochrane systematic review (n=8 studies comparing SAMe with placebo, imipramine, desipramine, or escitalopram, N=934 adults with MDD) showed that there are no differences in the depressive symptoms severity scores change between endpoint and baseline in patients treated with SAMe or placebo as monotherapy [71]. Low evidence quality supported a favorable effect of SAMe similar to imipramine when administered as monotherapy [71]. There was low-quality evidence that SAMe was superior to placebo as an add-on to SSRIs in the change of depressive symptoms severity from baseline to endpoint [71].

N-acetyl cysteine

This compound influences CNS activity through multiple mechanisms, i.e., it contributes to the production of glutathione and oxidative stress, and dysfunctions at this level have been frequently reported in many psychiatric disorders; also, it attenuates dopamine and glutamate dysfunctions in vitro, and it may be a useful adjuvant in the modulation of inflammatory pathways [72-74]. N-acetyl cysteine (NAC) is the acetylated form of cysteine and it is able to cross the blood-brain barrier [72]. The preclinical evidence in animal models of schizophrenia, bipolar disorder, MDD, anxiety disorders, and obsessive-compulsive disorders (OCD) spectrum disorders support the potential benefits of NAC administration [75].

Clinical evidence supports the use of NAC as an add-on treatment for patients with schizophrenia, with a favorable effect being reported on total and negative symptoms of psychosis [72]. A positive impact of NAC was observed in decreasing the craving and risk of relapse in patients with substance use disorders (SUDs), but proof of a clear effect of NAC on OCD spectrum disorders, ASD, and mood disorders is still lacking [72]. Orally administered NAC is considered safe and no severe tolerability problems have been detected in the clinical trials when recommended dosage (2000-2400 mg/day) was used [72].

In 24 patients with cannabis use disorders (CUD), NAC 1200 mg BID was administered for four weeks in an open-label design [76]. The treatment was well tolerated and had a favorable impact on the addictive pathology, decreasing the self-reported measures of marijuana use and craving [76]. The results of a mixed-models study (preclinical and clinical) indicated that NAC reduced the number of cigarettes smoked in patients with nicotine use disorder (NUD) [77]. In a group of treatment-refractory OCD patients (N=48), NAC (up to 2400 mg/day) was compared to a placebo for 12 weeks, and the results supported the efficacy of the active intervention, according to the Yale-Brown Obsessive Compulsive Scale (Y-BOCS); 52.6% of the NAC-receiving patients were full responders at the endpoint vs. only 15% in the placebo group [78]. NAC (1200-2400 mg/day) was also evaluated in a group of 50 patients with trichotillomania during a placebo-controlled randomized trial with a 12 weeks duration; NAC reduced significantly more than placebo the Massachusetts General Hospital Hair Pulling Scale (MGHPS) and the Psychiatric Institute Trichotillomania Scale (PITS) scores; 56% of the patients on NAC were “much” or “very much improved” vs. 16% on placebo [79]. A randomized, double-blind trial enrolled 66 participants diagnosed with excoriation (skin-picking) disorder who received NAC (1200-3000 mg/day) or placebo for 12 weeks; NAC was associated with significant improvements on the modified Y-BOCS vs. placebo at the endpoint; the overall tolerability of NAC was good [80].

Most studies evaluating NAC were underpowered and of short duration, which are important methodological limitations [75]. Therefore, although NAC demonstrated positive effects on animal models of psychiatric disorders, the clinical efficacy of this compound has not been fully explored [81].

Psychobiotics

Prebiotics, probiotics, and synbiotics have been explored in the treatment of psychiatric disorders based on their presumed properties of gut microbiota (GM) modulation. Potential mechanisms underlying their therapeutic effect in psychiatric disorders are very complex and include the participation of the immune system, vagus nerve, various neurotransmitters, and metabolic or endocrine factors [82].

Probiotics are defined as living organisms without pathogenic properties that can produce beneficial effects in hosts, and in this category are included a large variety of lactobacilli, bifidobacteria, strains of Escherichia coli, certain enterococci, Saccharomyces boulardii, etc. [83]. The probiotic products available on the market are usually containing a combination of strains, which makes quite challenging the interpretation of results in clinical trials exploring this intervention (i.e., high heterogeneity of the active product) [83]. Prebiotics are mainly fibers, non-digestible ingredients of the diet, that may have a positive impact on the host's health through different mechanisms, e.g., selective enhancement of the activity and/or growth of some GM genera [83]. Prebiotics are, for example, inulin and pectin, which have been associated with increased bioavailability and uptake of minerals, lower risk of cardiovascular disease, and promoted satiety and weight loss [83]. Synbiotics represent mixtures of pre and probiotics, which presumably improve the survival and implantation of live microbial dietary supplements in the gastrointestinal tract [83].

A meta-analysis (n=34 trials) concluded that prebiotics did not differ from placebo for depression or anxiety, while probiotics had small but significant effects for depression and anxiety [84]. Larger effects were reported for probiotics in clinical samples of depressed patients, than in community samples, but the pooled effects were low, due to a paucity of trials focused on mental health status-related outcomes [84]. According to another systematic review (n=54 randomized placebo-controlled trials) and meta-analysis (n=30 trials), the impact of most probiotics on mood, anxiety, depression, and psychiatric distress was not relevant vs. placebo at a qualitative level, but only at a quantitative level [85]. The same source concluded that depression severity and psychiatric distress registered but minor improvements in the probiotic group [85].

A systematic review (n=11 randomized controlled trials) showed that probiotics can be beneficial in MDD and AD, with potentially favorable effects in mania, by reducing the rehospitalization rate in these patients [86]. In the case of ASD, the results of the trials were mixed, but early-in-life administration of probiotics may have a preventive role [86]. The tolerability was good in most of the reviewed studies [86].

A randomized, double-blind, placebo-controlled trial enrolled 48 healthy adults with a body mass index (BMI) > 25 kg/m2 and investigated the impact of 21 g oligofructose/day or placebo (maltodextrin) for 12 weeks on food intake and related variables [87]. Body weight decreased by 0.45+/-0.31 kg during three months, and the self-reported caloric intake was correlated with a lower area under the curve (AUC) for ghrelin and a higher AUC for peptide YY in the oligofructose-receiving group [87]. Insulin concentrations mirrored the evolution of glucose, which decreased in the oligofructose group and increased in the control group at the endpoint vs. baseline [87]. The overall tolerability of oligofructose was good [87].

Another double-blind, randomized clinical trial explored the effect of supplementation with synbiotics and probiotics on mental health, quality of life, and anemia in patients undergoing hemodialysis for 12 weeks, and the results showed a significant decrease in BDI and Beck Anxiety Inventory (BAI) scores vs. placebo [88]. Health-related quality of life was not significantly improved by probiotics/synbiotics vs. placebo [88].

Minerals: Zinc, magnesium, copper, selenium, and iron

Micronutrients have been linked with the status of mental health and potential neuroprotective effects [89]. Selenium is important for the construction of selenoproteins, which are involved in the protection against oxidative stress in the CNS, and low selenium levels have been associated with cognitive loss and neurotransmitter turnover rate changes [89]. Zinc is involved in numerous cellular processes, potentially significant for the pathophysiology of depression and neurocognitive disorders; probable antidepressant effects of zinc may be mediated by its glutamatergic N-methyl-D-aspartate (NMDA) receptor antagonistic properties [89]. Copper homeostasis is important, and an excessive accumulation of this micronutrient leads to Wilson disease, which includes depressive and anxiety manifestations; copper could be involved in the neuroplasticity mediated by BDNF (brain-derived neurotrophic factor) and NGF (nerve growth factor); immune function could be affected by copper imbalances, and may influence the pathogenesis of depression [89]. Magnesium participates in the enhancement of DNA replication, transcription and translation, and it is a coenzyme or activator for many enzymatic systems; also, it is an NMDA glutamate receptor antagonist and is involved in memory functioning [89].

Micronutrient supplementation in healthy individuals has a limited favorable impact on mood and anxiety manifestations, but minor general improvements may still be reported [90]. In adults with physical or psychiatric conditions, the effect can be more favorable, although this consideration is limited by small samples and nutrient heterogeneity in the administered products [90]. Broad-spectrum nutrient products are preferable to a few preselected micronutrients [90].

A study exploring the long-term safety of micronutrients (N=17, average length of monitoring= 2.66 years) reported good preliminary tolerability and long-term safety [91]. The overall evaluation concluded that substantial psychiatric benefits outweigh the minimal risks reported in these patients

[91]. However, screening for potential medical diseases is recommended before the initiation of treatment with micronutrients, and long-term monitoring is also considered useful [91].

There are preliminary data about the potential benefits of micronutrients in autism, depressed mood, stress-related conditions, and elderly populations, but less significant benefits in individuals presenting with bipolar disorder, ADHD, and SUDs [92].

Inositol

This is a simple precursor included in the phosphatidylinositol cycle, a secondary messenger system important for CNS activity [93,94]. In patients with MDD, a low level of inositol in the cerebrospinal fluid (CSF) has been reported [93]. This compound was investigated in patients diagnosed with MDD, panic disorder, and OCD with positive results, while in cases of SSD, AD, ADHD, and ASD the results were negative [93]. In preclinical models, chronic administration of inositol reduced anxiety-like and depression-like behaviors in rats but did not lead to significant effects on amphetamine-induced hyperactivity, apomorphine-induced stereotypy, or on memory functioning in monkeys [94].

A meta-analysis of the trials focused on the effects of inositol in patients with depression and anxiety disorders (n=11 and 4 reports, respectively, reaching a total of 242 and 70 participants) did not detect statistically significant results vs. placebo on depressive, anxiety, and obsessive-compulsive symptoms [95]. The discontinuation rate reported in these trials was not significantly influenced by inositol, either [95]. The percentage of responders was marginally higher in the patients with depression treated with inositol vs. placebo, and patients with premenstrual dysphoric disorder had a trend towards a better evolution if they received inositol [95]. Gastrointestinal discomfort was reported marginally more frequently in patients treated with inositol compared to placebo [95].

Herbal products

St. John's wort, kava, Ginkgo biloba extract, and valerian are the most explored herbal supplements in patients with psychiatric disorders [96], but their efficacy is controversial due to many potential confounders: lack of adequate, good quality trials; the complexity of the standardized products investigated; difficulties in differentiating the effects of a herbal add-on from the effect of the concomitantly administered psychotropics, etc.

According to a review (n=9 controlled trials), while several studies reported herbs' superiority vs. placebo, others did not find differences between herbs and antidepressants in terms of effectiveness [96]. Kava has been associated with anxiolytic properties in studies with short duration; clinically significant improvements were detected during Ginkgo biloba administration in domains like memory impairments, concentration, fatigue, anxiety, and depressed mood; valerian may decrease sleep latency and nocturnal awakenings, but the effect was not consistently reported across studies as superior to placebo; St. John's wort was associated with positive results when administered for patients with depressive symptoms, but there are several negative studies, also [96].

Another review of studies exploring 27 herbal medicines and formulas in the treatment of psychiatric disorders reported that kava and St. John's wort benefit from good quality evidence in the treatment of anxiety and depression, respectively; other phytotherapies (saffron, passionflower, etc.) are not, at least for now, supported by enough data derived from well-designed trials [97].

Continuous research on the efficacy and safety of herbal products is necessary [98]. Although this type of therapeutic intervention has been increasingly explored and is an attractive alternative due to its potential superior tolerability and acceptability for patients with psychiatric disorders, clinicians must be aware of the limitations associated with the generally low-quality evidence on which such products are used [98].

DISCUSSION

The interest of clinicians and researchers in NP is increasing, and a continuously growing body of literature is published regarding the potential benefits of different nutritional interventions in patients with psychiatric disorders. This may be a consequence of the inherent limits of the pharmacological and psychotherapeutic interventions in this population, reflected in the high rate of non-response or partial response to conventional approaches. For example, more than one-third of all patients diagnosed with MDD have treatment resistance [99-101], and almost a quarter of individuals with FEP will become treatment-resistant in their early stages [102,103].

Omega-3 PUFAs were explored in clinical and epidemiological studies, meta-analyses, and systematic reviews, and the available evidence supports a potential benefit of this intervention in patients with MDD, ADHD, FEP, anxiety disorders, and AD [30,31,33-39]. The main positive effect involved in the PUFAs' favorable consequences, when used as an add-on to current psychiatric treatment, was supposed to be their influence on oxidative stress and lipid metabolism [34,39]. However, the number of reviewed sources was small, and the duration of the studies was too short to allow for definitive conclusions.

Healthy diets, especially Mediterranean, Norwegian, and Japanese, were explored in prospective clinical trials and literature reviews, and the main mechanism of action supposed for these interventions was an antiinflammatory activity [8,40-47]. The results of these interventions were positive in lowering the severity of MDD, ADHD, anxiety symptoms, depressive symptoms, and psychological stress, but also in increasing the quality of life in patients with depression [40-47]. The methodology of these sources was of moderate and high quality, but the high degree of heterogeneity of these diets prevents the extraction of clearly-cut recommendations.

Vitamins added to the diet as a therapeutic strategy (vitamins B1, B6, B12, D, and folate) were also explored in clinical and preclinical studies, reviews, and meta-analyses, with mixed results [48-53,55-64]. Except for some well-established recommendations, e.g., vitamin B1 for Wernicke encephalopathy and Korsakoff syndrome, other psychiatric disorders, like MDD, bipolar disorder, ASD, anxiety disorders, and SSD, are still explored as potential targets for vitamin therapy. The potential beneficial effect of B vitamins in slowing cognitive decline is also a subject of interest for researchers [52]. The main mechanism of action of vitamin therapy is patients with psychiatric disorders is supposed to be this intervention's positive effects on multiple metabolic processes within the CNS.

Preclinical studies, clinical trials, reviews, and meta-analyses regarding the effects of SAMe and NAC were analyzed [66-81]. While SAMe benefits from good-quality evidence to be recommended in patients with MDD, due to its efficacy comparable to that of certain antidepressants, the main recommendation for NAC regards the patients with SUD (especially NUD and CUD) [66,70,71,76-78]. The importance of NAC and SAMe on the normal function of neurotransmission has been supported by preclinical models [66,81], but the positive results obtained on preclinical models for a diversity of psychiatric disorders were not yet confirmed in clinical trials [75].

Psychobiotics interfere with the microbiome-gut-brain axis and data about prebiotics and synbiotics are encouraging in MDD, ASD, and anxiety disorders, but not so much for AD, according to the primary and secondary sources reviewed [84-88]. Micronutrients lead to minor general improvements in mood and anxiety symptoms, and preliminary data about their usefulness in ASD, stress-related conditions, and elderly populations also exist [90,92]. The number of reviewed sources for this intervention was low; therefore it could be expected that further research may change its level of recommendation. Inositol was associated with good results in MDD, panic disorder, and OCD, and negative results in SSD, AD, ADHD, and ASD, according to limited sources [93-95]. Herbal products are largely used nowadays, but the evidence to support their evidence is scarce; according to the reviews analyzed here, kava may be useful for the treatment of anxiety symptoms (on short duration) and St.John's wort for depressive symptoms [96,97]. It is important to note that NP interventions have been associated with good tolerability, and no significant adverse events were reported in the reviewed reports.

These conclusions about mixed results of NP interventions support the results of other available secondary reports. For example, a meta-analysis concluded that the response to treatment in the case of adding ω-3 PUFAs and zinc in patients with MDD and antidepressant treatment was similar [103]. Folic acid was not supported by studies in terms of efficacy; the preliminary data for inositol was negative, and the evidence for vitamin D was considered scarce [104]. Mixed results also were reported for vitamin B12 and SAMe [104]. Another review of 356 sources concluded that the highest therapeutic potential in the prevention or treatment of psychiatric disorders can be attributed to the rational diet, physical activity, use of psychobiotics, and consumption of antioxidants [11].

There are a large number of ongoing studies that approach the subject of psychobiotics augmentation in patients with psychiatric disorders. For example, the augmentation of antipsychotic treatment with probiotics (bifidobacteria, lactobacillus, and maltodextrin) or prebiotics (inulin + maltodextrin) in patients with schizophrenia is intended to be explored in a 26-week prospective, randomized, controlled multicenter trial [108]. Dietary supplements (microbiotherapy, GynMDD) are explored as add-ons to venlafaxine in patients with MDD in a 12-week randomized trial, after failure of a first-line antidepressant [109]. The exploration of a potentially favorable impact of prebiotics (Akkermanisa muciniphila, through enteric-coated orally-administered acetate) on the most problematic side effects of psychotropics, i.e., weight gain and metabolic syndrome, is the objective of a 5-month trial, which is expected to enroll 16-25-year old patients undergoing psychiatric treatment [110]. In children, the effects of probiotics, more specifically a combination of BB-12 and LGG (Lacticaseibacillus rhamnosus GG and Bifidobacterium animalis subsp. lactis) are explored in a randomized, placebo-controlled trial with an expected target of enrollment of 70 patients (4-16-year old) with confirmed ASD, who will be monitored for 84 days [111].

It is expected that further research in the field of nutritional interventions for psychiatric disorders would include long-term, double-blind, controlled design, in order to obtain high-quality data. Also, decreasing the heterogeneity of the study population would be beneficial for detecting a signal in efficacy studies. This objective can be attained by different means, such as using structured interviews, excluding different confounders (like concomitant use of antibiotics for studies with psychobiotics), and applying cut-off values at baseline for certain psychological instruments used to quantify the severity of core psychiatric symptoms.

Limitations of this review refer to its narrative design, due to which certain important sources may be missed. However, based on the reviewed material, a systematic review of the nutritional interventions, and even an umbrella review, may be granted. Also, due to its design, there was no structured assessment of the quality of evidence; therefore reports of different design and methodological quality have been treated equally. There are some data about the utility of fecal material transplantation in patients with psychiatric disorders, and about the potential benefits of cannabinoids [6,105-107], but these aspects were not approached because it was appreciated that they would increase too much the heterogeneity of the explored interventions.

As strengths of this review, it is important to mention its aim, i.e., to explore the available evidence for the nutritional interventions both at clinical and preclinical levels. Also, the inclusion of a large variety of psychiatric disorders undergoing intense exploration from the perspective of NP may be considered another strength. Last but not least, the awareness of available nutritional interventions is still precarious in mental health specialists, therefore, a presentation of the current trends, challenges, and perspectives in the field of NP was considered beneficial for the case managers responsible for treating patients with psychiatric disorders

CONCLUSION

NP is still a young science and the systematic exploration of its core interventions requires intensive investigation in good-quality, large-scale trials, before they can be included in the therapeutical guidelines. Based on this review of the literature, preliminary data to support the use of omega-3 PUFAs, healthy diets, vitamin therapy, SAMe, NAC, psychobiotics, micronutrients, inositol, and herbal products exist, and most of the evidence refers to potential benefits of these augmentative strategies in patients with anxiety and depressive symptoms. The translation of data from preclinical models to clinical populations is difficult, and a difference between the results in animal studies and those in human trials has been reported. The main advantages of NP interventions refer to their good tolerability, their superior acceptability (due to lower stigma), and their flexibility, which allows to use them as add-ons to other treatments.

Authors' contribution
OV conceived the idea of the review. OV, AGM, BMP and CFP designed the study. OV, CFP, AGM, CFP, DU, MM, CF, AID, CN and CAS screened the studies during the primary search. OV, AGM and CAS drafted the first version of the review. OV, CFP, DU, MM, CF, CN and CAS revised the manuscript and elaborated the conclusions of the review. All authors had full access to the data contained in this review and decided to submit the manuscript for publication.

Abstract: *Mental disorders clearly are among the major challenges of global health causing many concerns for health systems, health experts, and health policy makers. The present study was conducted to evaluate the mental health program in comprehensive health centers and health houses under the coverage of Ilam University of Medical Sciences in the West of Iran. The present study was conducted based on the reports obtained from the mental health program in 2019. The data were recorded into registration and evaluation forms of mental disorders with the codes 102-19-03 and 102-19-01 and then entered into the Excel software. The prevalence per 100 and 100,000 people, as well as their 95% confidence intervals were calculated using Formula 1 ROUND (Number of cases*100000/population) and Formula 2 ROUND (Prevalence ±1.96*SQRT (Prevalence *(1-Prevalence)/population). The results showed that the prevalence of depression was 19,100 [95% CI: 18999-19201] 19100), and the prevalence of anxiety was 304,66 [95% CI: 20348-30584] per 100,000 population. The highest prevalence among mental disorders was related to depression and anxiety. Considering the high average score of mental health status in people over 65 years old, it is necessary to implement measures and interventions to improve these individuals' mental condition and upgrade their mental health.*

Keywords: *Spatial analysis; Ilam province; Mental health; Iran*

INTRODUCTION

According to the definition provided by the World Health Organization (WHO), mental health is "a health status that turns one's potential talents into reality, enabling people to cope with routine life tensions, accomplish valuable work, and upgrade their social participation" [1]. Mental health is an important component for evaluating the health status of a population and can be evaluated using various indicators [2]. In other words, the concept of mental health falls under the general concept of health and refers to all the methods and measures used to prevent people from developing mental disorders, as well as for the treatment and rehabilitation of affected individuals. Psychologists believe that mental health can be affected by individual characteristics, mental and environmental burdens, economic, social, and familial status, failure to achieve life goals, and lack of motivation [3]. Industrialization of countries, the growth of urbanization, migration to cities, etc. are phenomena that are associated with numerous troubles, including psychological and social problems. For this reason, mental health and mental disorders are considered top priorities in today's world. The high prevalence of mental disorders and their associated morbidities render them an immediate health priority [4].

Excessive attention to physical health problems (such as infectious and contagious diseases) has caused mental health to receive less priority in many countries around the world, including its social and spiritual aspects, which have been overlooked in most cases [5]. Statistics on the global burden of mental illnesses highlight the need to pay attention to these aspects more than ever. In parallel with the estimation of the WHO, Harvard University and the World Bank declared that mental disorders were responsible for about 13% of the total burden of diseases in 2006, which was predicted to reach 15% by 2020. The rate of morbidities caused by these disorders has been reported beyond 33% [6]. In Iran, mental health disorders account for 14.5% of the total burden of diseases, and after traffic accidents, they share the second rank with cardiovascular diseases. In women, depression claims the first place of disease burden, while in men, addiction is considered the third cause of disease burden [7]. According to studies in Iran on individuals older than 15 years old, the prevalence of mental disorders has been 25.9% in women and 14.9% in men, and it was reported that overall, 21% of people suffered from some sort of mental problems. Some studies have assessed the prevalence of mental disorders in Ilam province{8]. In a population-based study by Visani et al. [9], the prevalence of DSM-IV mental disorders in both genders was investigated in the urban areas of Ilam province. Out of 763 participants aged 15 years and older in the recent study, 25.8% showed symptoms of mental distress, and the prevalence of mental disorders was reported to be 20.9% in men and 29.8% in women. Also, the prevalence of anxiety, major depressive disorder (MDD), and obsessive-compulsive disorder was higher in women than in men (23.6% vs. 18.2%; 22.7% vs. 17.4%; 13.9% vs. 10%, respectively). In women, the prevalence of phobia was reported as 10.4%.

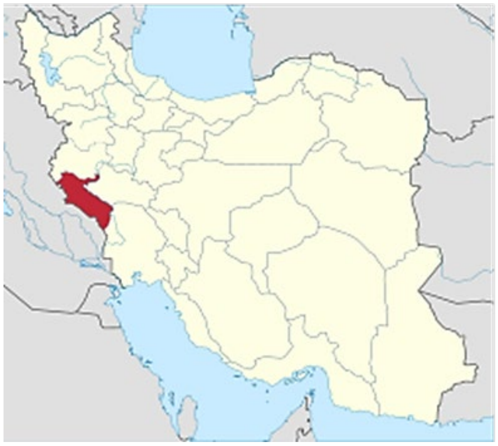
Studying mental health status can provide managers and decision-makers of organizations with valuable information for planning educational, therapeutic, and preventive measures to reduce the incidence of these diseases in society. Such information can be obtained by monitoring the mental health status of people in different societies [5].

Assessment and monitoring of mental disorders in the country and in Ilam province can help better understand the condition of mental health and public health in society, which is an important and influential factor affecting social productivity and wealth creation. Therefore, researchers here aimed to investigate the mental health status of the urban population of Ilam using the data recorded in the registration and assessment forms designed for mental disorders. Furthermore, we evaluated the mental health program performed in comprehensive health centers and health houses covered by the Ilam University of Medical Sciences in the West of Iran.

MATERIALS AND METHODS

The present cross-sectional study was conducted on the basis of the reports derived from the mental health program in Ilam province in 2020. According to the statistics announced in 2021, Ilam province harbors a population of over 630,000 people living in ten cities: Ilam, Ivan, Chardavl, Sirvan, Malekshahi, Mehran, Abdanan, Dehloran, Badreh, and Darrehshahr (Figure 1).

Figure 1: The geographical location of Ilam province



This study was conducted to assess the mental health program implemented in the comprehensive health centers and health houses affiliated with the Ilam University of Medical Sciences in 2019. The study was approved by the institutional ethics committee under the code IR.MEDILAM.REC.1399.266. The data were gathered by reviewing registration and evaluation forms for mental disorders with the codes 102-19-03 and 102-19-01 in all ten cities of Ilam province. Then based on the population of each city in 2021, the prevalence of mental disorders was calculated in 100 and 100,000 people.

Analytic Method

After collection, the data of each city were entered into Microsoft Excel software, and formulas 1 and 2 were used to calculate the prevalence of mental disorders (with 95% CIs) in 100 and 100,000 people.

Formula 1: ROUND (Number of cases*100000/population)

Formula 2: ROUND Prevalence ±1.96*SQRT (Prevalence *(1-Prevalence)/population)

Also, to determine the geographical distribution of mental disorders in the cities of Ilam province, the commands of spatial analysis in the STATA 11 software (Stata Corp. LLC College Station, Texas, USA) were used.

RESULTS

The results showed that in Ilam province, the prevalence of depression was 19100 (95% CI: 18999-19201), and the prevalence of anxiety was 30466 (95% CI: 20348-30584) per 100,000 people. According to the results, the highest prevalence among mental disorders was related to depression and anxiety. The highest rate of depression belonged to Ilam (20300, 95% CI: 20137-20463) and Malekshahi (21836, 95% I: 21297-22375) cities, while the lowest rate of depression was reported in Sirvan (16292, 95% CI: 15691-16897) and Badreh

(17299, 95% CI: 16706-17892). Also, the highest rates of anxiety were recorded in the cities of Abdanan (22298, 95% CI: 21922-22674), Ivan (22559, 95% CI: 22228-22970), and Ilam (21200, 95% CI: 210135-21365). On the other hand, the cities of Sirvan (16769, 95% CI: 16184-17404), Chardavl (16499, 95% CI: 16228-16770), and Darrehshahr (19099, 95% CI: 17790-18408) had the lowest rate of anxiety (Table 1).

Table 1: The prevalence of depression and anxiety in the population of Ilam province per 100,000 people in separate cities

Location	Population	Major Depressive Disorder Prevalence		Anxiety Disorder Prevalence	
		Number of cases	Rate per 100,000 (CI95%)	Number of cases	Rate per 100,000 (CI95%)
Ilam	235144	47734	20300 (20137-20463)	49850	21200 (210135-21365)
Abdanan	46977	9630	20499 (20134-20463)	10475	22298 (21922-22674)
Ivan	48833	10236	20961 (20600-21322)	11036	22559 (22228-22970)
Mehran	27506	5281	19199 (18734-19664)	6162	22402 (21909-22895)
Badreh	15614	2701	17299 (16706-17892)	2701	17299 (16706-17892)
Dehloran	66339	13135	19800 (19497-20103)	12538	18900 (18602-19198)
Darrehshahr	59551	10838	18200 (17890-18510)	10778	18099 (17790-18408)
Shirvan	14404	2347	1294 (15691-16897)	2419	16796 (16184-17404)
Chardavl	72167	12412	17199 (16924-17474)	11907	16499 (16228-16770)
Malekshahi	22587	4932	21836 (21297-22375)	3884	17196 (16704-17668)
Total	580148	110808	19100 (18999-19201)	176750	30466 (20348-30584)

Regarding age distribution, the results showed that the highest prevalence of depression (29%), anxiety (35.5%), and psychotic disorder (22.6%) was observed in people over 65 years of age. The psychological disorders of mania (6.3%) and obsessive-compulsive disorder (13.3%) were more commonly observed in the age group of 15-24 years compared to other age groups. Regarding the gender distribution of mental disorders, it was noticed that depression (20.3% vs. 22.7%), mania (2.6% vs. 4.7%), anxiety (23.6% vs. 32.18%), obsessive-compulsive disorder (10% vs. 13.79%), phobia (10.4% vs. 5%), and psychotic disorder (6.17% vs. 2.4%) were more frequent in women than in men (Table 2).

Table 2: The prevalence of mental disorders in Ilam province in various age groups and genders

Age groups/ gender	Depression	Mania	Anxiety	Obsessive-compulsive disorder	Phobia	Psychotic
	Prevalence (CI 95%)	Prevalence (CI 95%)	Prevalence (CI 95%)	Prevalence (CI 95%)	Prevalence (CI 95%)	Prevalence (CI 95%)
15-24 years	14.0 (7.08-15.1)	6.3 (5.9-7.3)	14.7 (12.1-16.8)	13.3 (9.04-15.15)	8.4 (6.9-11.1)	0.7 (0.01-5.9)
25-44 years	20.6 (18.2-22.3)	4.0 (2.6-9.1)	21.2 (16.2-18.2)	11.3 (9.13-14.2)	7.5 (6.9-11.1)	4.8 (3.6-6.3)
55-64 years	22.7 (20.2-24.3)	2.3 (1.4-2.9)	23.6 (20.3-25.2)	13.4 (8.1-16.1)	8.3 (7.9-11.3)	3.7 (1.2-5.7)
> 65 years	23.6 (20.3-25.2)	0.4 (0.1-1.1)	35.5 (32.3-37.8)	9.7 (7.1-11.2)	9.7 (7.1-12.2)	22.6 (20.2-27.6)
Male	17.4 (15.1-19.6)	2.6 (1.3-8.7)	18.2 (15.2-21.1)	10.0 (8.1-12.4)	5.0 (3.7-8.2)	2.4 (1.4-4.1)

The results of spatial analysis regarding the geographical distribution of mental disorders in Ilam province showed that depression, anxiety, and mania were more commonly observed in the northern compared to southern regions of the province, showing the highest prevalence in Ivan City. Also, panic disorder was more prevalent in southern cities of the province (Abdanan and Dehloran) than in other cities (Figure 2).

DISCUSSION

Sciences. The results of the present study showed that the highest prevalence of depression, anxiety, and psychotic disorders was observed in people over 65 years old. In this study, age showed a direct and significant correlation with having unsatisfactory mental health, indicating the importance of advancing age in the development of mental health problems such as depression, anxiety, and psychotic disorders. In other words, the incidence of mental health disorders increased with age, contradicting the findings of Heidari et al. [10] and Jafari et al. [11]. In recent studies, a higher age was reported to be significantly associated with more favorable mental health. Other studies; however, have reported a significant relationship between mental health and advancing age, including a report by Visani et al. [12]. In another study, Noorbala et al. [13] noted that with increasing age, the likelihood of the development of mental disorders increased so the highest prevalence (49.9%) was related to people over the age of 65 years. Among the reasons for the higher prevalence of mental health disorders in older people are retirement, menopause, loneliness-associated anxiety, and biological alterations. The results of these studies are generally consistent with our findings; nevertheless, some discrepancies can be explained by differences in the assessment tools employed and the age spectra of the studied populations.

Figure 2: The results of spatial analysis. Geographical distribution of the most common mental disorders in Ilam province

The results of this study showed that the highest prevalence of panic disorder and obsessive-compulsive disorder was related to the age group of 15-24 years. Mental disorders in teenagers and young adults exacerbate the predicted future burden of diseases and adversely affect numerous life aspects, including educational performance, employment, income, personal relationships, and social participation, as well as the workforce [14]. In a study in Brazil conducted on individuals aged 18 years and older, it was shown that younger people were more vulnerable to mental problems [15]. In another study in Iran, Shirzadi et al. [16] declared a higher prevalence of these disorders in people aged 41 years or older compared to 18-40-year-old individuals.

Also, the results of the present study revealed a lower prevalence of depression and anxiety in women than in men. In a study, Falahzadeh and Momayezi [17], who investigated the prevalence of depression, anxiety, and stress in Yazd City, Iran, noted that depression, anxiety, and stress were more prevalent in women than in men, and this difference was statistically significant for anxiety (P=0.01) and stress (P=0.02), which was not consistent with our observation.

We also noticed a higher prevalence of obsessive-compulsive disorders, phobia, and psychotic disorders in women compared to men, which was in agreement with the reports of Pendrez et al. [18], Kesler et al. [19], and Chang et al. [20]. The higher prevalence of mental disorders in women compared to men can be attributed to biological factors, gender-related differences, environmental and occupational stress, as well as limited sources of satisfaction and social participation of females.

Although in the present study, a significant portion of the urban population declared that they had unsatisfactory mental health conditions, this may not exactly match the clinical definition of adverse mental health. Therefore, the results of such subjective studies should not be regarded as a basis for judgment about the true condition of the mental health of respondents. Nevertheless, one should admit that a ratio of people, especially among women, suffer from some degree of mental health disorders. In this regard, the key measures that can be taken may be to initially achieve a correct understanding of the issue and then to implement comprehensive interventions for monitoring populations as large as possible, especially among vulnerable groups.

Numerous viable strategies are available to maintain and improve public health. For example, unemployment has been pointed out as an important factor contributing to the development of mental health disorders [21]. So, an important intervention that governments can employ is to create more jobs, especially for youth, and to improve people’s livelihoods as much as possible.

Also, another effective measure for improving mental health is to remove the sources of distress, psychological pressure, and unnecessary tensions, which can be achieved with the help of mass media by nurturing a comfortable atmosphere. Moreover, the establishment of psychological counseling clinics can be among low-cost and beneficial measures to cover a large population, including young people, middle-aged, and elderly people, so that they can amend and improve their mental health**.**

CONCLUSION

The results of this study affirmed a relatively high prevalence of suspected mental health problems among people over 65 years of age, which is an alarming call, requiring authorities and researchers to pay more attention to this issue and to identify and modify the factors affecting the mental health of these people. A unique observation in this study was the lower prevalence of anxiety and depression in women than in men. Also, we noticed that panic disorder and obsessive-compulsive disorder were most prevalent in the age group of 15-24 years. A reduction in the prevalence of mental disorders can enhance social liveliness. In this regard, increasing people’s awareness of ways to reduce mental disorders, expanding psychological counseling centers across the city, establishing counseling phone lines, residing counselors and psychologists in public places such as mosques, expansion of parks and enjoyable environments, equipping parks with sports devices, and finally, encouraging people to use these services can help reduce depression and anxiety in society.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. The source of the funding code is the code of IR.MEDILAM.REC.1399.266.

Abstract: *Boosted by the COVID-19 pandemic, the adoption of technology has shifted people's lifestyles, impacting social interactions and leading to an increase in the use of telemedicine, including teledermatology (TD). Social media platforms facilitate communication between patients and physicians, between primary care physicians and specialists, and between dermatologists. The study aimed to assess the attitudes, views, and usage of dermatologists regarding TD consultations. A cross-sectional study was performed with the use of an anonymous, web-based questionnaire intended to be completed by dermatologists. A total number of 73 physicians, both resident and board-certified dermatologists completed the survey. Almost everyone (98.6%) used some form of teledermatology, the most frequently used platforms being WhatsApp, followed by classical telephone calls/messages, email, and other forms of TD. TD is considered to be especially useful in communicating with peer colleagues (94.4%), with physicians of other specialties (90.0%), with family doctors (72.9%) and with patients (69.9%). Since TD can facilitate the treatment-related follow-up of adverse effects, while also being useful in the triage of patients, its use will likely increase in the future. The main concerns were related to the accuracy of the diagnosis through TD, a less developed doctor-patient relationship, a less informative consultation, an increased workload as well and a diminished financial reimbursement. Dermatologists currently use TD in addition to the classical consultations of patients, as well as to communicate with family physicians and peer colleagues to better manage complex cases. Furthermore, TD proves to be an important tool in the education of young dermatologists.*

Keywords: *teledermatology, consultations, education*

INTRODUCTION

Skin diseases are frequent pathologies encountered in the general population that require standard or specialized care, depending on disease rarity or difficulty. The Global Burden Disease study that was performed over 10 years in 187 countries revealed that skin conditions ranged from the 2nd to the 11th leading cause of years lived with disability, and, at a global level, cutaneous conditions were the 4th cause of nonfatal disease burden [1]. Such a high prevalence of skin disorders is met with a significant effort on the part of the medical personnel and the medical system, requiring new solutions to optimize medical care. Teledermatology (TD) developed in recent years as a response to this need. Its use, boosted by the COVID-19 pandemic [2], is expected to increase soon. Technology facilitates professional communication between patients and healthcare providers, as well as between healthcare professionals of identical or different specialties.

Several social media platforms facilitate communication between patients and healthcare providers, allowing individuals to contact specialized personnel more quickly. During the past years, departments already offering asynchronous TD created new systems to support the direct interaction between specialists and patients [3].

As expected, the use of TD increased along with other branches of Telemedicine, such as Tele-echography[4], women's health telemedicine, family medicine telemedicine, telecardiology, and others. Taking into consideration these changes in technology and social interactions, we aimed to evaluate the attitudes, views, and usage patterns of dermatologists.

MATERIALS AND METHODS

A cross-sectional study was performed between February and July 2022 among specialist and resident dermatologists using a web-based survey. Contact details were retrieved from the database of the Dermatology Department at the University of Medicine and Pharmacy "I. Hatieganu" Cluj Napoca, Romania. Both email and phone messages were used to distribute the questionnaire to dermatologists, explaining that the completion of the survey was anonymous and voluntary.

The survey was developed by the authors based on previously published data and was sent via Google Forms (Google LLC, Mountain View, CA, USA) to the participants. The questionnaire was divided into several sections: Initially, the participants were invited to provide certain anonymous personal data such as age, gender, area of dwelling, workplace, and amount of time spent using appliances such as telephone, tablet, etc. This introductory part was followed by a second section assessing the current use of TD, a section focusing on the accuracy of medical consultation via TD, the advantages and disadvantages of TD, and future perspectives.

Statistical analysis

Data was collected and further analyzed using SPSS, version 12, SPSS Inc., Chicago, IL, USA. Spearman correlation was used between ordinal variables and between ordinal and numeric variables. The biserial correlation coefficient was used between ordinal and nominal variables. A p-value under 0.05 was considered statistically significant.

RESULTS

A total of 73 participants completed the online questionnaire, of which 25 (34.2%) were during residency and 48 (65.8%) were board-certified dermatologists (Table 1). The female gender predominated with 65 answers (89%), with the following age distribution: 20 participants (27.4%) in the 20–30-year age group, 27 (37%) in the 30–40-year age group, 16 (21.9%) in the 40-50 year age group and 10 (13.6%) above 50 years. Most responders worked under contract with the national health care system, while 12 (16.4%) participants only worked in private settings. 72 (98.6%) out of 73 responders use some form of TD, the most frequently utilized platform being WhatsApp with 69 users (95.8%), followed by classical telephone call/message in 52 participants (76.5%) and email-based TD in 35 participants (57.4%) (Figure 1). TD is being used for the diagnosis and treatment of dermatological disorders daily by 23 (31.5%) participants and every few days by 30 (41.1%) participants.

Table 1: Participant characteristics

Total no of responders	**73**	
	No	**%**
Gender		
Female	65	89%
Male	8	11%
Area of dwelling		
Urban	73	100%
Years in practice		
0-10 years	24	32.9%
11-20	11	15.1%
21-30	5	6.8%
31+	8	11%
Current resident	25	34.2%
Setting		
Out-patient clinic public	11	15.1%
Out-patient clinic private	10	13.7%
Inpatient public	23	31.5%
Both public and private settings	27	37%
Inpatient private	2	2.7%

TD is being used as a tool to professionally discuss cases between peer colleagues daily by 21 (29.2%), every few days by 27 (37.5%), once a week by 10 (13.9%), and less than once a week by 14 (19.4%) of participants.

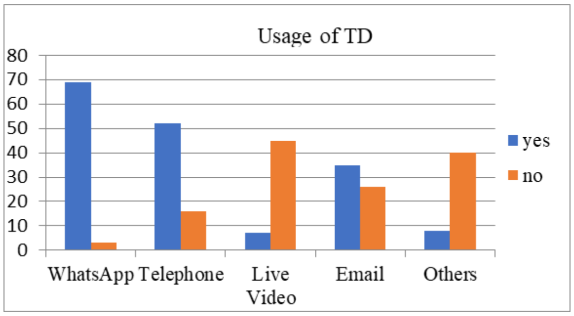

Figure 1: Usage of TD among dermatologists

TD is considered to be most useful as tertiary TD, in communicating with peer dermatologists, with 68 (94.4%) affirmative responses; it may be useful to some extent to communicate with physicians of other specialties 63 (90.0%), with family doctors 51 (72.9%) and with patients 51 (69.9%). Only 4 responders (5.5%) consider that TD did not increase workload, while 19 physicians (26.0%) consider that the workload mostly increased during their free time and 48 (65.8%) realized that TD-related tasks surged both during working hours and leisure period (Figure 2).

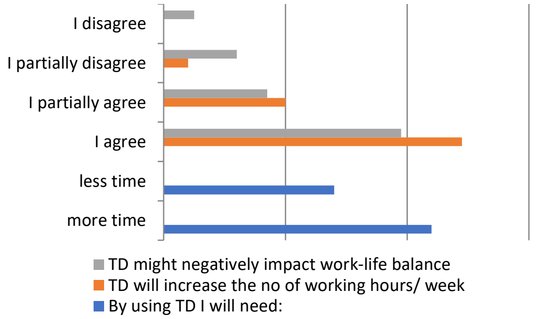

Figure 2: TD and work-life Balance

58 (79.5%) participants agreed to some extent that the relationship between a patient and the physician may be less developed in a TD setting and 67 (91.8%) responders contend that it may be less informative compared to classical consultations. Most replies, 55 (75.3%), were not reimbursed for the service of TD consultations; for 7 (9.6%) it was expected from the work environment, while another 7 (9.65) were partially or fully reimbursed 4 (5.5%).

41 (56.2%) dermatologists agree that consultations performed via TD might have a lower accuracy compared to classical consultations, while 29 (39.7%) partially agreed with this statement; clear images, complete anamnesis, and communication with the patient were considered key factors that might enhance diagnostic accuracy. Both forms of TD, synchronous and asynchronous TD, were considered as having advantages and disadvantages. Participants were asked the most common pathology they were contacted for during the last week through TD and the most frequent skin disorders were allergic reactions with 25 (34.7%) answers, acne with 10 answers (13.9%), bacterial infections with 7 (9.7%), followed by viral infections and malignant lesions with 6 (8.3%) answers each. Most dermatologists 61 (83.6%) felt uncomfortable offering medical information regarding malignant cutaneous pathology through TD. Physicians partially agree 38 (52.1%) and agree 22 (30.1%) that TD may facilitate the follow-up of treatment related to adverse effects. Regarding the statement that TD will increase the number of working hours/week, 49 (67.1%) agreed and 20 (27.4%) partially agreed. A large number of responders, 45 (61.6%) agreed and 24 (32.9%) partially agreed that TD might negatively impact the work-life balance. Participants agreed in 53.4% (39 answers) and partially agreed in 23.3% (17 answers) that by using TD many patients trivialize the dermatological consultation. Also, dermatologists feel that TD should be financially sustained in 76.4% (55) of answers or partially agree with the statement in 20.8% (15). In our cohort, 51 (69.8%) physicians believe that they will use more TD in the future. 41 (56.2%) agree and 28 (38.4%) partially agree that this rise will be due to patients request. Most health care professionals agree 29 (39.7%) and partially agree 31 (42.5%) that TD could be employed as a useful method in the triage of patients.

Upon statistical analysis, age was inversely correlated with the custom of discussing certain cases with colleagues ($p=0.009$), with the utility of TD with the family doctor ($p=0.018$) and peer dermatologists ($p=0.02$), with the future usage of TD ($p=0.015$) and the utility of TD in the triage of patients ($p=0.015$). The usefulness of TD in communicating with the patient and with general practitioners was correlated with the usefulness of TD as a tool in the triage of patients ($p<0.1$ and $p=0.01$). Future use of TD was inversely correlated with a less developed doctor-patient relationship ($p<0.01$), with a lower diagnostic accuracy ($p<0.01$), with the trivialization of consultation ($p<0.01$) and longer working hours ($p<0.01$) and positively related to better monitoring of adverse effects ($p=0.0$). Lack of information through TD was related to more time invested by the physician ($p<0.01$) and inversely correlated with monitoring of adverse effects ($p=0.02$). The lack of accuracy of TD was also related to more time invested by the physician ($p<0.01$) and longer working hours ($p<0.01$). Disturbance of work-life balance was related to more time required by TD ($p=0.05$) and consult trivialization ($p<0.01$). Finding a financial solution for TD was related to better monitoring of adverse effects through TD ($p<0.01$).

DISCUSSION

A relatively high usage of TD was noticed in our cohort, with 53 (72.6%) participants employing it a few times a week. Taking into account that 60 (82.2%) participants consider that TD could be a useful method for selecting patients in the future, we believe that some of these consultations are aimed at prioritizing patients according to pathology. Indeed, TD might be useful in the triage of patients, its' cost- effectiveness increasing when patients need to travel farther distances to benefit from the dermatological service [5].

Tertiary dermatology, or a "second opinion" among specialists, is a valuable tool for reinforcing or modulating the physician's perspective on certain pathology but also as a learning tool for residents/young specialists. In our study, TD was used for the means of tertiary dermatology by 48 (66.7%) participants daily or every few days and once or less than once a week by 24 (23.3%) participants. The vast majority of our responders, 68 (94.4%), considered TD as being useful in communicating with peer colleagues while younger age was also correlated with the use of TD in communicating with peer colleagues, family, or specialist physicians. A recent systematic review that focused on TD education both in medical students and postgraduate trainees indicated high satisfaction rates and improvement in educational outcomes among medical students, residents, and other trainees, some residents mentioning that TD provided a low-stress learning environment and some students considering that eConsult-based training enhanced their education [6,7].

Secondary to tertiary-care teleconsultation is applied less frequently, however, a study performed in the Netherlands that included 39 dermatologists showed that it had important advantages such as fast response time, formalized records, and data and privacy security(6). However, physicians also prefer to use means of communication they are accustomed to because of ease of use and direct personal network[8,9]. A study evaluating practice models in TD in Spain indicated that the main advantages of TD were prioritization in cancer screening, rapid emergency care, training of and communication with primary care physicians, and screening for trivial conditions while also reducing in-person visits [10]. A TD service between primary healthcare centers and the National Skin Centre in Singapore using "store and forward TD" indicated satisfaction for the TD service (by both primary and specialist doctors), more convenience for the patients but also an educational value for family physicians, while considering challenging the quality of the images, lack of personal assessment of the skin pathology and of the patient as a whole [11,12].

In our study, 56 (76.7%) agreed (fully or to a certain extent) that patients trivialize dermatological consultations when performed as TD. This usually implies a lack of complete information regarding the skin problem but also carelessness regarding compensation, leading to incomplete medical advice and frustration.

Financial aspects will directly influence the usage of TD. A cross-sectional study performed in the US involving 591 dermatologists documented low reimbursement (69.8%) as one of the most common barriers to the implementation of TD while the majority of respondents (85.2%) felt reimbursement for store-and-forward TD was too low [13]. A global survey developed by WHO in 2010 indicated that TD is more acknowledged in high-income countries, difficulties in implementing were legal issues concerning the privacy of patients, limited reimbursement for practitioners as well and competing health system priorities. High costs are also an issue in developing countries, alongside resource, infrastructure, and technical limitations [14,15]. Therefore, we may observe that financial issues do influence in different manners the implementation and use of TD. In certain areas, specialists do not receive extra compensation for addressing professional questions from primary care physicians but time slots in the weekly schedule were allocated for such tasks, integrating TD alongside other tasks [16].

In our cohort, the use of TD has increased workload both during working hours and in free time, physicians expect a further increase in the future while 69 (94.5%) dermatologists partially/completely agree to the fact that TD might negatively impact the work-life balance. A cross-sectional study evaluating usage patterns on WhatsApp TD (WhatsApp being the most frequently used platform in our study as well) underlined the fact that the added workload both during and after work hours was the biggest disadvantage of WhatsApp, potentially leading to burnout. Both primary health care physicians, as well as specialists, reported being consulted during working hours but also after 20:00, during weekends, holidays, or when abroad [16].

The most common pathologies dermatologists were contacted for were allergic reactions, acne, bacterial and viral infections as well as malignant lesions. A study performed in pediatric patients described acne, atopic dermatitis, benign melanocytic nevi, and verruca as being the most common diseases treated by TD in the adolescent age group. In contrast, atopic dermatitis, verruca, and molluscum were the most frequent diseases in the 3-12 year age group [17]. Most dermatologists who participated in the survey considered that TD might have a lower accuracy compared to classical consultations. This concern has previously been reported by US-based pediatric dermatologists who, even though positive about TD's present and prospects, considered TD as being inferior to in-person care regarding accuracy and management plans [9,18]. This may pose the specialist in an uncomfortable position, having to give a diagnosis and offer a treatment plan while not being fully confident of the diagnosis. However, this situation is avoided when there is a face-to-face meeting for the initial diagnosis and the monitoring is performed by TD. A randomized clinical trial including patients with atopic dermatitis, where the initial visit was in-person while the follow-up was through TD versus personal consultation for a year, showed similar improvement in the disease severity of patients [19]. A similarly structured- study demonstrated that the quality of life of patients with atopic dermatitis improved both when followed up through TD or in person [20]. Very good results for monitoring were also obtained for store-and-forward TD in case of pathologies like acne and psoriasis [21].

When asked about which pathologies they felt uncomfortable offering consultation through TD, 59 (80.8%) answered malignant tumoral lesions. Indeed, the accuracy of TD in skin neoplasms was inconsistent between studies, with a moderate accuracy reported by Giavina-Bianchi et al [22] and a high accuracy reported by Moreno-Ramirez et al [23] and Kroemer et al [24]. One should take into consideration that diagnostic precision increases when both clinical and dermoscopic images are available, but, also the cautiousness of dermatologists of not missing a melanoma and, while a severe dysplastic nevus would still be in a "benign" category, the excision of such a lesion would be in the benefit of the patient. Another aspect to take into consideration is that dermatological consultation of patients referred through TD detected "unobserved" malignant lesions both on exposed and covered skin [25], highlighting the usefulness of intertwining both methods of consultation.

The future perspectives of TD look promising. Most of our participants 51 (69.8%) agreed or partially agreed to the statement that they will be using TD in the future and 69 (94.6%) to the statement that it will requested by patients in the future. A cross-sectional study performed in the US aiming at dermatologists also showed that 70.9% of the physicians foresee that TD could become an ongoing component of their practice, provided that reimbursement for video visits remains similar to that of in-person visits [9].

Among the limits our study has, we would like to mention that participants were selected from the database of the clinic, therefore, we believe most answers were from the Transylvanian part of the country. Number of participants can virtually always be increased to obtain more accurate results. Still, we believe the data we obtained is relevant, especially because the official implementation of TD differs more between employers and the type of work setting compared to a certain region in the country. Rapid development of social media platforms and artificial intelligence quickly alters the work environment for dermatologists, leading to changes in perception and usage that only be captured by repetitive assessments performed at different time-frames**.**

CONCLUSION

In conclusion, dermatologists currently use TD in addition to classical consultations for patients, to manage cases from family physicians but also to discuss and better manage complex cases. TD proves to be an important tool in the education of young dermatologists. The swift evolution of technology brought us this tool that is under continuous development but that is here to stay.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research received no external funding.

Authors' contribution

Conceptualization, CE, MNM, AB; methodology, CE, MNM, SD.; software, PAI; validation, all authors; investigation, CE, MNM, F.S.; data curation, SD, PAI., A.N.; writing—CE, X.X., F.S., M.C.D.; writing—review and editing, all authors. All authors have read and agreed to the published version of the manuscript.

Ethics approval and consent to participate

The study was conducted following the Declaration of Helsinki, and approved by the Institutional Review Board (or Ethics Committee) of the University of Medicine and Pharmacy "I. Hatieganu" Cluj Napoca number 172.

Acknowledgments

The authors would like to express heartfelt gratitude to Miss Adriana Pop for her valuable editing skills.

Supplementary material – Dermatologists' views on the use of teledermatology

Within the first section, anonymous personal data was collected through several questions. Participants had the option of selecting gender, area of the dwelling, and age (by selecting between age groups, namely "20-30","30-40","40-50", "50-60", "60-70" and ">70"), the setting they provide dermatological health care ("public ambulatory", "private ambulatory", "public hospital", "private hospital" and "public & private ambulatory/hospital") and the years of clinical experience ("Resident", "Specialist for 0-10 years", "Specialist for 10-20 years", "Specialist for 20-30 years", "Specialist for 30-40 years" and finally "Specialist for >40 years"). A question assessing the time of current use of computer/tablet/phone/television was included in the survey but due to its lack of statistical significance, it was not reported in the manuscript. The second section of the questionnaire focused on the current use of Teledermatology. Participants were first asked to express the method they currently employ for TD by choosing from the following possible answers: "WhatsApp messenger", "Telephone", "Email", "Live Video conferencing" and "other devices". To assess the frequency of TD in skin disease diagnosis/treatment and the frequency of using TD in the management of cases, four possible answers were offered to the two questions: "never", "daily", "every couple of days", "once per week", "less than once per week". To evaluate the workload, the statement "The use of TD increased my workload during:" was followed by four possible answers "working hours", "free time", "both working hours and free time" and "it did not increase my workload". The following question referred specifically to the impact of COVID-19 on TD, asking "Usage of TD increased:" with the following answers: "during the COVID-19 pandemic", "after the COVID-19 pandemic" and "COVID-19 did not influence the usage". Regarding compensation, participants were asked whether they received any benefits for TD consultations and also whether they believed they were supposed to; responders had the option of selecting the following: "Yes", "No", "Partially" and "not applicable (part of the contract)".

To answer the questions of whether through TD the doctor-patient relationship is less developed and the TD-consultation is less informative, four choices were given: "I don't agree, I don't agree, I partially agree, I agree". Participants were given the option of selecting "yes, no, partially agree" to whether TD is more useful in communicating with patients, family physicians, dermatologists, and other specialists.

The next section of the questionnaire was directed towards how physicians feel about their diagnostic accuracy through TD. To the question of whether TD- followed diagnosis accuracy could be lower compared to in-person consultations and whether accuracy increases when collaborating with family physicians, the answer options were: I don't agree", "I rather not agree", "I agree partially" and "I agree". To improve the diagnostic accuracy in TD, the following options were given: "Clear images with optimal resolution", "Complete information from anamnesis", "Prior appointment for the TD consultation", "the presence of a dialogue with the patient". In the following question, dermatologists could select which type of TD is more useful, what was the cutaneous pathology they were most frequently contacted for during the last week and what is the pathology for which they don't feel comfortable offering TD-consultations.

To evaluate the workload, participants were asked whether they would be more or less time-efficient by using TD and whether the use of TD would increase the number of working hours/week. The agreement of participants regarding the trivialization of consultation, regarding ease in the follow-up of treatment-related adverse effects was also assessed.

Future perspectives and usage trends of TD were assessed by asking physicians whether they believe they will use more TD in the future, whether they believe patients will request more TD in the future, whether TD could be an option for triage, whether TD would affect their work-life balance and whether the future of TD would depend on finding a financial reimbursement, with the following scale of agreement: "I don't agree", "I rather not agree", "I agree partially" and "I agree".

Nevertheless, throughout the study, all participants had the chance to add personal ideas after each section, if they wanted to express answers that were not displayed.

Abstract: *A rare zoonotic disease, monkeypox is brought on by the Monkeypox virus, which is a member of the Orthopoxvirus genus, Chordopoxvirinae subfamily, and Poxviridae family. Smallpox-like symptoms are brought on by the monkeypox disease, which is closely linked to the variola virus (smallpox virus). In the past, it has been demonstrated that smallpox vaccination with the vaccinia virus (another orthopoxvirus) is 85% protective against monkeypox. The two most likely forms of monkeypox transmission are animal-human transmission and human-human transmission. Transmission between people has been connected to respiratory droplets, coming into contact with bodily fluids, contaminated patient things or surroundings, and skin lesions on infected people. Numerous strategies or tactics have been developed by monkeypox to subvert or exacerbate the host's immune reaction to infection. A crucial element of innate immunity, natural killer [NK] cells employ cytokines to kill virus-infected cells and interfere with the operation of other cell types like T cells and dendritic cells. Studies have shown that the smallpox vaccine provides cross-protection against other Orthopoxvirus species, including monkeypox. This study was out to provide a thorough overview of the pathogenesis, prevention, risks, immune response problems, and analysis of possible concerns associated with the monkeypox virus.*

Keywords: *Monkeypox, pathogenesis, prevention, threats, challenges, immune response*

INTRODUCTION

Numerous levels of worry, terror, mistrust, and rumors have been circulated among the general public as a result of the quick spread of new diseases. Rapid scientific knowledge dissemination is a useful strategy for reducing the fear and worry that emerge with new outbreaks. This won't be possible unless epidemiologists and statistical modelers offer in-the-moment studies to forecast future conditions and potential treatment effects [1]. In order to solve the health issue as soon as is practical, it should be underlined that real-time analysis is the analysis of fresh available data utilizing logic and mathematics as soon as the data is created. In Wuhan, China, instances of pneumonia with no known cause were first reported in late December 2019. A unique form of coronavirus was later found to be the source of those pneumonia cases in January 2020 [2]. The World Health Organization (WHO) officially named the ailment COVID-19 (short for coronavirus illness 2019), and the virus was given the moniker SARSCOV-2 (severe acute respiratory syndrome coronavirus 2). Iran and other nations across the world made major steps in this direction despite the COVID-19 epidemic being alarming and it being crucial to design and implement appropriate regulations [3]. In Wuhan, China, instances of pneumonia with no known cause were first reported in late December 2019. A unique form of coronavirus was later found to be the source of those pneumonia cases in January 2020. The World Health Organization (WHO) officially named the ailment COVID-19 (short for coronavirus illness 2019), and the virus was given the moniker SARSCOV-2 (severe acute respiratory syndrome coronavirus 2). Iran and other nations across the world made major steps in this direction despite the COVID-19 epidemic being alarming and it being crucial to design and implement appropriate regulations [4]. Since the late 1970s, there have been no confirmed cases of smallpox. As a result of their disease, up to 30% of people passed away. Toximemia and systemic shock, a condition that affects the entire body, were the causes of death (toxins in the blood). This study set out to provide a thorough overview of the pathogenesis of the monkeypox virus, its hazards, obstacles to the immune system's response, and an analysis of potential threats.

SMALLPOX

In a second outbreak, up to 80% of household contacts could contract the highly contagious disease known as smallpox. Those who survived the illness typically experienced long-term effects like blindness and significant scarring [5]. In order to continue studying vaccines and treatments, researchers saved some samples of the smallpox-causing variola virus. Only two locations on Earth contain these virus samples. They are secure at the State Research Center of Virology and Biotechnology in Russia and the Centers for Disease Control and Prevention (CDC) in Atlanta (VECTOR Institute). Public health officials are only concerned about smallpox spreading as a result of biological warfare because it is no longer present in nature [6]. There hasn't been any recent evidence of terrorists using smallpox as a weapon. On the other side, scientists are prepared to react if smallpox is employed as a weapon. The CDC has enough smallpox vaccine to protect everyone living in the United States in the event that the virus reappears. The variola virus is what causes smallpox. In the past, prolonged, direct face-to-face contact with people was the main method of spreading smallpox. When they coughed or sneezed, respiratory particles would travel through the air. If other people inhaled these large drops, they would catch the infection [7]. A less frequent way for people to contract an infection is by direct contact with the rash or crust material from a swab. People can pass the virus to one another by sharing linens, towels, and clothing. The condition is most contagious when throat and mouth ulcers initially appear. On the other hand, smallpox remains contagious for a number of weeks after the initial lesions manifest. Since smallpox no longer occurs naturally, smallpox diagnoses are extremely uncommon today. Any symptoms you have are almost always a sign of another illness or condition [8]. Prior to its elimination, smallpox was easy to distinguish from a few other common illnesses, such as severe chickenpox. If other people breathed in these large drops, they would catch the infection. A less frequent way for people to contract an infection is by direct contact with the rash or crust material from a swab. People can pass the virus to one another by sharing linens, towels, and clothing. The condition is most contagious when throat and mouth ulcers initially appear. Contrarily, smallpox is infectious for several weeks following the onset of the first lesions [9]. Since smallpox no longer occurs naturally, smallpox diagnoses are extremely uncommon today. Any symptoms you experience are almost certainly a sign of another illness. Prior to its elimination, smallpox was easy to distinguish from a few other common illnesses, such as severe chickenpox. Human monkeypox was discovered in 1970 after regional smallpox elimination revealed isolated cases of a comparable illness in remote areas of the DRC. Since then, extensive research has been done on the epidemiological and clinical features of the condition, but no specific medical countermeasures have been created [10]. It could take anywhere between 5 and 21 days from the moment of exposure to the onset of symptoms. On average, symptoms endure between two and four weeks. Although it is unknown to what extent it can happen without symptoms, there may be very few indicators.

MONKEYPOX

There is currently no known animal reservoir host for the zoonosis monkeypox (Figure 1), making preventative strategies challenging. In addition to the DRC (CAR), cases have recently been reported from Nigeria, the Republic of the Congo (ROC), Sierra Leone, Liberia, Cameroon, and the Central African Republic [11].

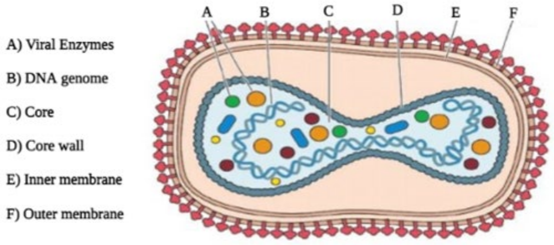

Figure 1: Structure of Monkeypox

In several of these nations, there had been no reports of human monkeypox for decades. The cessation of routine smallpox immunization, which led to a decline in orthopoxvirus immunity, has been blamed for the rise in cases of monkeypox. Since May 13, 2022, cases of monkeypox have been reported to WHO from 12 Member States that are not endemic for the virus and span three WHO regions. Epidemiological research is ongoing, but to date, there have been no established links to travel to endemic regions [12]. According to the information that is currently available, occurrences have mainly — but not exclusively — been found among men who have sex with men (MSM) who visit general care and sexual health clinics for treatment. This Disease Outbreak News aims to raise awareness, offer technical support for urgently advised measures, and provide information to support readiness and response operations. The situation is evolving, and according to WHO, additional cases of monkeypox will be discovered as surveillance in non-endemic countries increases [13]. In order to stop the disease from spreading further, the first step will be to accurately notify those who are most at risk of contracting monkeypox. The most vulnerable individuals, according to the available studies, are those who have had close personal contact with a monkeypox patient. The WHO is also creating policies to safeguard frontline healthcare providers and other vulnerable healthcare employees, such as housekeepers. The WHO will offer more technical recommendations over the coming days [14].

Monkeypox signs and symptoms

Early signs of monkeypox frequently include headaches, muscle pains, fever, and fatigue, thus they may initially resemble the flu (Figure 2). Swollen glands are a symptom of the illness, which might mimic chickenpox, measles, or smallpox. These generally show up behind the ear, below the jaw, in the neck, or in the groin before the rash does. After a few days of the fever, lesions often start on the face before spreading centrifugally to the palms of the hands and soles of the feet [15].

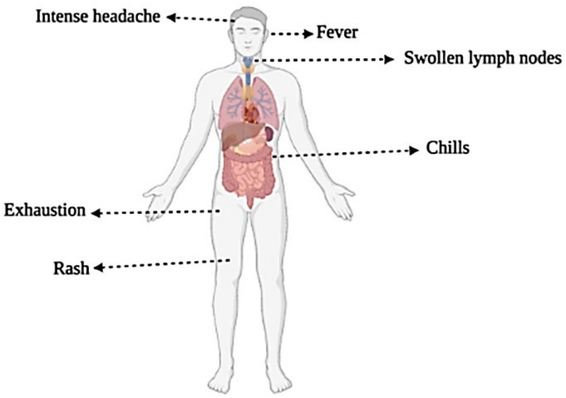

Figure 2: Symptoms of monkeypox disease (illness lasts for 2-3 weeks)

Patients with HIV may have a number of symptoms. Several people in the 2022 monkeypox outbreak also experienced fever, swollen lymph nodes, and difficulties swallowing in addition to vaginal and perianal lesions. One in five infected people have lesions in their eyes, more than two-thirds have lesions in their mouths, more than two-thirds have lesions in their genital area, and more than two-thirds have lesions on their palms and soles. They begin as little flat patches, then transform into tiny lumps, filling with clear, then yellow fluid, finally bursting and scarring [16]. There may be a few or many thousand lesions, which occasionally combine to form larger lesions. Every area of the body that is afflicted by lesions develops at the same stage. It resembles a smallpox rash in appearance. The rash often lasts for ten days or less. Affected people may feel under the weather for two to four weeks. After the lesions have healed, they may leave behind pale marks before leaving behind black scars. Only a small amount of infection from person to person has been observed in Africa's disease-endemic regions [17].

Pathogenesis of monkeypox

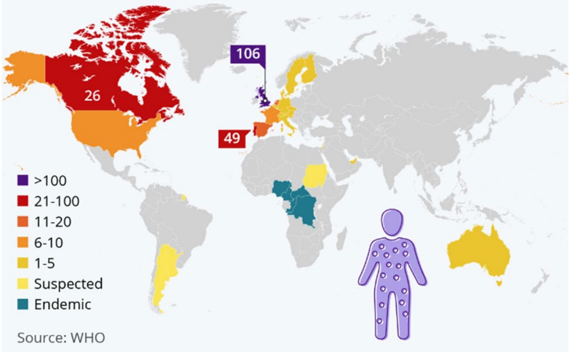
With the exception of the fact that viral entry from a wildlife source most frequently occurs through small lesions on the skin or oral mucous membranes, the pathogenesis of human monkeypox is substantially the same as that of smallpox. Viral entry can also happen through the respiratory tract in rare instances of person-to-person transmission. Although the monkeypox virus replicates in lymphoid tissue similarly to the smallpox virus, it results in greater lymphadenopathy [18]. The virus initially manifests in mononuclear phagocytic cells, moves through the bloodstream, and eventually resurfaces in skin cells. The virus swiftly infects nearby lymph nodes after an infection. On the third or fourth day following infection, the virus enters the bloodstream and moves to the bone marrow, sleep, and other lymph nodes. Once the virus has been in the blood for 8 to 12 days, fever and toxemia set in [19]. The virus has now been localized in the oral mucosa and dermal blood vessels, resulting in the initial enanthem and exanthem. By day 14, the host is contagious, and high viral titers are found in the kidneys, liver, spleen, lymph nodes, and bone marrow. Skin lesions develop as a result of endothelial cell vessel walls and dermal capillaries dilating [20]. When these lesions reach the epidermis, swelling cells eventually grow so enormous that their membranes rupture. Pus forms after vesicular lesions as a result of the concentration of polymorph nuclear cells inside the vesicle. The legions scramble when the pus progressively vanishes. The most frequent cause of mortality is overwhelming toxemia, which is most likely brought on by circulating immune complexes. The long-term repercussions of secondary infections include encephalitis, blindness, and arthritis [21].

Epidemiology of the disease

While clinically less severe than smallpox, monkeypox is a viral zoonosis (a virus that spreads from animals to people) with symptoms that are strikingly similar to those experienced by smallpox patients in the past. It is brought on by the orthopoxvirus genus monkey poxvirus, which is a member of the Poxviridae family. The West African and Congo Basin (Central African) clades of the monkeypox virus are separated. Monkeypox is the name given to the virus because it was originally identified in primates in a Danish laboratory in 1958. [22]. The first human case was found in a child in the Democratic Republic of the Congo in 1970. The monkeypox virus can be transferred from one person to another by close contact with lesions, bodily fluids, respiratory droplets, and infected surfaces like beds. Monkeypox can incubate for anywhere from 5 and 21 days, but it typically takes 6 to 13 days. Numerous animal species have been identified to be susceptible to the monkeypox virus's contagiousness [23]. Further investigation is required to identify the precise reservoir(s) and how virus circulation is maintained in nature because the natural history of the monkeypox virus is still unknown. Eating raw meat and other animal products from diseased animals may pose a risk [24]. Although it can be severe in some people, such as children, expectant mothers, or those whose immune systems have been weakened by other illnesses, monkeypox is typically self-limiting. With a case fatality rate of 3.6% compared to 10.6% for the Congo Basin clade, the West African clade appears to induce less severe disease in humans [25].

Geographical distribution and high-risk areas

With 106 persons confirmed to have the disease as of May 26, 2022, the UK has the highest number of cases in a non-endemic country, according to the WHO, followed by 49 people in Portugal and 26 in Canada (Figure 3).



Source: WHO

Figure 3: Number of recorded monkeypox cases per country (May 13-26, 2022) and where the disease is endemic (Source WHO).

No fatalities have been connected to the incident as of yet. In the instances that have been recorded so far, there have been no confirmed travel connections to an endemic region [26]. According to the information that is currently available, occurrences have mainly — but not exclusively — been found among men who have sex with men (MSM) who visit general care and sexual health clinics for treatment. All cases whose samples had the West African lineage of the virus confirmed by PCR to date have been identified. A genomic sequencing from a swab sample from a confirmed case in Portugal showed a close match to the monkeypox virus driving the current outbreak to cases shipped from Nigeria to the United Kingdom, Israel, and Singapore in 2018 and 2019. [27]. Finding confirmed and probable cases of monkeypox without any known travel history to an endemic region is unusual. Until recently, surveillance in non-endemic areas was minimal, but it is currently being increased. According to the WHO, more instances are anticipated to be reported in non-endemic regions. The research suggests that those who come into contact with symptomatic instances directly on a bodily level are where human-to-human transmission happens [28]. Aside from this new epidemic, WHO continues to receive data through established surveillance techniques on the status of ongoing cases of monkeypox in endemic countries (Integrated Disease Surveillance and Response). Monkeypox is endemic in Benin, Cameroon, Central African Republic, Gabon, Ghana (only in animals), Ivory Coast, Liberia, Nigeria, Republic of the Congo, Sierra Leone, South Sudan, and the Central African Republic [29].

WHO risk assessment

Only West and Central Africa often experience the endemic monkeypox disease. There is an urgent need to increase awareness of monkeypox and carry out thorough case finding and isolation [along with supportive care], contact tracing, and supportive care to prevent further onward transmission because it is unusual to find confirmed and suspected cases of monkeypox in multiple countries without a history of travel to an endemic area [30]. Cross-protective immunity from smallpox immunization will be restricted to the elderly since populations under the age of 40 or 50 no longer benefit from the protection offered by prior smallpox vaccination programs. Younger individuals have only a limited level of immunity to monkeypox because the virus has not been seen in non-endemic regions. In the past, it has been discovered that the smallpox vaccine can prevent monkeypox [31]. Despite the licensing of one vaccine (MVA-BN) and one specific treatment (Tecovirimat) for monkeypox in 2019 and 2022, respectively, these preventative interventions are still not generally accessible. According to the information that is currently available, occurrences have mainly — but not exclusively — been found among men who have sex with men (MSM) who visit general care and sexual health clinics for treatment. No fatalities have been noted to date [32]. The extent of local transmission is currently uncertain, though, because of the scant observation. There is a good likelihood that other cases, including in different population subgroups, with unidentified transmission networks, will be found. Cases of monkeypox have been recorded in several countries spanning several WHO regions, and it is very likely that cases will be found in more nations [33]. The situation is evolving, and according to WHO, additional cases of monkeypox will be discovered as surveillance in non-endemic nations grows. So far, there have been no fatalities connected to this outbreak. The first efforts should concentrate on informing those most at risk of monkeypox infection accurately, stopping the disease's spread, and safeguarding first responders [34].

Host Immune Responses to Monkeypox

Poxviruses have developed a variety of methods or tactics to circumvent or worsen the host's immune reaction to infection. Although much study has been done on the pathology and pathogenesis of monkeypox, the innate and adaptive immune responses to monkeypox infection are still poorly understood due to a paucity of data. A crucial element of innate immunity, natural killer (NK) cells employ cytokines to kill virus-infected cells and interfere with the function of other cell types like T cells and dendritic cells [35]. Activating or inhibitory NK cell receptors engage with their ligands, such as major histocompatibility complex 1 (MHC-1) molecules, to cause activation or inhibition of NK cells. Granule secretion, which includes perforin and granzyme, and cell-cell contacts are the mechanisms by which NK cells carry out their killing activity. IFN- and TNF-, which are generated by NK cells in the early stages of infection, regulate dendritic cells to polarize T-helper type 1 (Th1) cells and mediate inflammatory responses in inflamed tissues [36]. Infections with human monkeypox have not been associated with T cell or antibody responses in Nigeria. Additionally, there are no data or reports on the immunological reactions that occur after experimental infections in animal models. An immunologically naive population that is very susceptible to monkeypox infection has been caused by the lack of cross-protection produced by the smallpox vaccination, as well as the probable weakening of herd immunity and immunosuppression as a result of HIV/ AIDS. This may be the cause of the current global resurgence of monkeypox (Figure 4) [37].

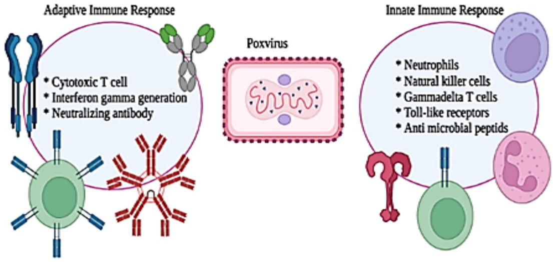


Figure 4: Host Immune Responses to Monkeypox

Prevention and Vaccination

It is expected that smallpox vaccination will protect against human monkeypox infection because the two viruses are closely related and the vaccine shields animals from lethal monkeypox challenges in experiments. This has not been properly demonstrated in individuals because systematic smallpox immunization was stopped when smallpox was eradicated. The smallpox vaccine has been demonstrated to reduce the risk of monkeypox in previously immunized individuals in Africa. A reduction in poxvirus immunity in communities that have been exposed affects the occurrence of monkeypox [38]. It is attributed to a rising proportion of unvaccinated people as well as a decline in cross-protective immunity among those who received an immunization before the cessation of mass smallpox vaccinations in 1980. The US Centers for Disease Control and Prevention (CDC) advises being vaccinated against smallpox in order to protect themselves from the disease if they are going to be handling sick people or animals or looking into outbreaks of monkeypox. Anyone who has had close or direct contact with people or animals that have monkeypox infection is also advised to get vaccinated [39]. The CDC advises against pre-exposure immunization for veterinary professionals, veterinary assistants, and animal control officers unless they are taking part in field investigations. The CDC advises healthcare professionals to put on a full set of personal protective equipment before treating an infected person (PPE). Included are a gown, mask, pair of goggles, and a disposable filtering respirator (such as an N95). An infected person should be isolated in a negative air pressure chamber or, at the very least, a private exam room to prevent others from coming into touch with them [40]. In the United States and the European Union, Tecovirimat has a license to treat a variety of poxviruses, including monkeypox. BMJ Best Practice recommends tecovirimat or the smallpox drug Brincidofovir, together with supportive care, if antiviral treatment is required [including antipyretic, fluid balance, and oxygenation]. Aciclovir or empirical antibiotic therapy may be used if a subsequent bacterial or varicella zoster infection is suspected [41].

AN ANALYSIS OF POTENTIAL THREATS

While the COVID-19 epidemic is still going strong, other viral diseases are starting to show warning symptoms in various nations around the world. Since the disease's initial identification in 1958, small, recurring outbreaks of monkeypox have been noted. However, with 100 confirmed cases and almost 300 suspected cases recorded in more than 16 countries, we are now witnessing a larger spread of the virus [42]. 13 solitary cases of monkeypox have been documented in recent years, the majority in a single nation. The virus can be found in Central and West Africa, where it is believed to be present. Three cases of monkeypox were reported in Britain in May and June 2021; each case was linked to travel to West Africa. The World Health Organization claims that the current outbreak is different and that there are far more cases, more cases of human-to-human transmission, and more cases of infection outside of Africa [43]. Although there is limited human-to-human transmission, monkeypox is typically spread from diseased animals to humans in Central and West Africa. Before skin irritation manifests as blisters on the skin, mouth, genitals, eyes, or soles of the feet, smallpox first causes fever, headache, exhaustion, and enlarged lymph nodes. It's probable that the short-term increase in instances of monkeypox transmission has resulted from the resumed travel and big social gatherings after the coronary limitations were loosened [44]. Although current statistics indicate that this strain of the virus is quite similar to the West African variant that has previously caused modest outbreaks, it is also likely that the virus has been changed or modified to allow for wider transmission. However, because of prior coronary infections, this outbreak could develop differently [45]. Our immune systems can be affected by infections from the COVID-19 virus, and current research from Australian experts reveals that this condition may last for weeks to months after the initial infection. According to scientists, it's also conceivable that this immunological dysfunction may modify clinical illness, accelerate viral transmission, or raise vulnerability to infection [46]. Despite the peculiarity of the present monkeypox epidemic, the US Centers for Disease Control and Prevention predict that there will certainly be more in the following weeks. It takes some time to determine the entire scope of an epidemic since symptoms can appear up to three weeks after exposure and the virus can spread for up to a month. Given that the primary way that monkeypox is transmitted is via intimate contact with someone who has a rash or blister, it is unlikely that the illness will provide a fresh hazard at this time [47].

CONCLUSION

Considering what has been said so far, healthcare executives ought to provide staff members with the proper training in four areas: potential threats, prevention, detection, and care, as well as reporting.

Potential threats: Monkeypox is most commonly transferred by intimate contact with someone who has a rash or blister, thus under the current circumstances it is unlikely that the illness would pose a new threat.

Prevention: Direct contact with an infected person, especially sexual contact, puts one at risk for contracting monkeypox. Self-protection measures include avoiding skin-to-skin or face-to-face contact with people who are exhibiting symptoms, engaging in safer sex, washing your hands often with soap and water or an alcohol-based hand rub, and following respiratory etiquette.

Detection and care: People should visit their doctor and get tested for monkeypox if they get a rash that is accompanied by a fever, a feeling of discomfort or sickness, or both. If you have monkeypox, you should stay home until the scabs come off and avoid intercourse, especially oral sex. Patients can get supportive care to ease their monkeypox symptoms throughout this period. Anyone providing care for someone who has monkeypox should take the necessary measures, such as donning a mask and wiping down all objects and surfaces that have been touched.

Reporting: As soon as possible after returning home, anybody with a rash-like illness should consult a doctor and provide information about all recent travel, sexual history, and smallpox vaccinations. Avoid interacting with ill animals including rats, marsupials, and nonhuman primates (alive or dead), as well as eating or handling wild game, if you reside in or visit a country where monkeypox is prevalent (bush meat).

Abstract: *Gynecologic cancers are among the most common cancers in women and are a significant cause of mortality in women worldwide. FDG-PET images play a critical role in several areas of oncology and are an essential tool for the diagnosis and staging of gynecologic cancer, providing information about tumor metabolism. Aim: The aim of this study was to investigate the relationship between tumor differentiation, type of malignancy, and glucose metabolism in patients with confirmed gynecologic cancer. Materials and Methods We performed a retrospective review of 60 consecutive patients (ages 31-76) with histopathologically confirmed gynecologic cancer who underwent PET-CT in our department between January 2021 and March 2022. Quantitative data on glucose metabolism were collected using the maximum standardized uptake value normalized by lean body mass (SULmax). We reviewed a total of 60 patients with a mean age of 60±9 years, and a median of 62. Results: 14 patients were diagnosed with cervical cancer, 20 with endometrial cancer, and 26 with ovarian cancer; 13 patients had well-differentiated cancer, 11 had moderately differentiated cancer, and 36 had poorly differentiated cancer. A positive correlation was observed between the measured SULmax and the degree of tumor differentiation, indicating higher glucose uptake in poorly differentiated cancer. When examining the relationship between the type of cancer and SULmax, we found that endometrial cancer exhibited the highest mean SULmax (8.36±6.75), followed by ovarian cancer and cervical cancer. Additionally, we noted that glucose uptake was higher in patients aged over 62 years. Regardless of the tumor differentiation, the findings in endometrial cancer showed the highest mean SUVmax values in all grades of tumor differentiation. Conclusion: Our study showed that glucose consumption correlates not only with the degree of differentiation but also with age and type of tumor, with the highest values in patients older than 62 years with endometrial cancer. Given the correlation between glucose consumption and tumor aggressiveness, this finding may be important for prognostic evaluation of patients with gynecologic malignancies.*

BACKGROUND

Gynecologic cancers are among the most common cancers in women and are a major cause of mortality in women worldwide. There are five main types of gynecologic cancers: cervical cancer, ovarian cancer, uterine cancer, vaginal and vulvar cancer.

Despite advances in diagnosis, gynecologic cancers remain a major health problem worldwide, with a large number of cases already in a locally advanced stage of the disease at presentation.

Of all gynecologic cancers, only cervical cancer has screening tests that can detect it at an early stage when treatment is most effective. However, despite existing screening programs, cervical cancer is the third most common cancer in women worldwide [1]. With the exception of cervical cancer, there is no simple and reliable method for early detection of gynecologic cancers, making it especially important to recognize the warning signs.

Based on histologic criteria, gynecologic cancers are classified into three grades. Grading is a measure of cell differentiation in the tumor, based on the similarity of the tumor to the tissue of origin. The grade describes the appearance of the cancer cells as follows: Grade 1 (G1; well differentiated) and Grade 2 (G2; moderately differentiated) are the most common categories, while Grade 3 (G3; poorly differentiated) indicates a very aggressive tumor [2].

Positron emission tomography (PET) with fluorine-18-fluorodeoxyglucose (FDG) is an important tool for the diagnosis and staging of gynecologic cancer, providing information about tumor metabolism [3].

FDG-PET images play a critical role in several areas of oncology, primarily because of its ability to detect metabolic changes that may occur earlier and provide more meaningful insights into the effects of therapy compared with morphologic changes alone [4]. As detected by FDG-PET, tumor metabolic activity can provide a faster and more accurate assessment of treatment response. This allows physicians to assess the effectiveness of therapies earlier and adjust treatment plans in a timely manner if needed. By providing valuable metabolic information, FDG-PET contributes to more precise and personalized cancer management that can support treatment decision-making and improve patient outcomes [5].

PET is used in conjunction with computed tomography (CT) to precisely localize regions of increased focal uptake and to compensate for the attenuation effect of incident photons (attenuation correction). With the introduction of integrated PET/CT scanners, the limitations associated with inadequate anatomical definition of functional examinations have been overcome and image quality has been significantly improved [6,7].

In routine clinical practice, PET lesions are analyzed using the standardized uptake value (SUV), a semiquantitative parameter that allows assessment of metabolic activity but is also useful for quantifying the post-therapeutic metabolic response of the tumor. Since 1999, the European Organization for Research and Treatment of Cancer (EORTC) has introduced metabolic criteria that use the standardized uptake value (SUV) in positron emission tomography (PET) to evaluate the response to therapy. These criteria were developed to assess tumor metabolic activity and monitor changes in SUV levels before and after treatment. By analyzing SUV values, these criteria are expected to provide valuable information about the efficacy of cancer treatments and support clinical decision-making [8].

Response to therapy can also be assessed using CT imaging according to the Response Evaluation Criteria in Solid Tumors, but these criteria do not reflect metabolic changes. Tumors detected by morphologic imaging may contain nonviable necrotic tissue. Therefore, measurements from PET may provide more accurate information than a purely anatomic evaluation such as CT [9,10].

The aim of this retrospective study was to investigate the relationship between glucose metabolism, characterized by the uptake of 18F-FDG, measured by the maximum standardized uptake value normalized to lean body mass (SULmax), tumor differentiation, and the type of gynecologic cancer. The study was performed on the 3 major types of gynecologic malignancies – cervical, endometrial, and ovarian cancer.

MATERIALS AND METHODS

Patients

We retrospectively reviewed 60 patients with a type of gynecologic cancer aged 31 to 76 years who underwent FDG-PET/CT between January 2021 and March 2022. PET/CT images were evaluated for primary tumors, locoregional spread, and distant metastases. Quantitative data were collected using the maximum standardized uptake value normalized to lean body mass (SULmax) calculated in the pathologic regions of interest.

PET-CT imaging

PET/CT examinations were performed at the Central Emergency Military University Hospital in Bucharest, Romania, using a dedicated scanner. The weight and blood glucose level of each patient were measured before the examination. The actual injected and residual radioactive doses were also measured.

Before the scan, patients fasted for 6 hours, and only patients with a serum glucose level of < 200mg/dl were injected intravenously with 18F-FDG. Image acquisition started 50-60 minutes after injection. Patients were positioned with their arms raised above their heads. All examinations were performed according to a standard protocol, scanning from tentorium to mid-thigh.

PET/CT data analysis

Maximum SUV normalized to lean body mass (SULmax), was determined from FDG-PET studies and was measured in primary tumors (when possible) and in secondary lesions.

Statistical data analysis

The mean SUV was calculated for each type of cancer and for each of the three grades of differentiation.

RESULTS

From January 2021 to March 2022, a total of 60 patients with a mean age of 60±9 years, and a median of 62, were enrolled in the study. Of these, 14 patients were diagnosed with cervical cancer, 20 with endometrial cancer, and 26 with ovarian cancer. After analyzing the grade of tumor differentiation, we found that 13 patients were diagnosed with well-differentiated cancer, 11 patients with moderately differentiated cancer, and 36 patients with poorly differentiated cancer (Figure 1).

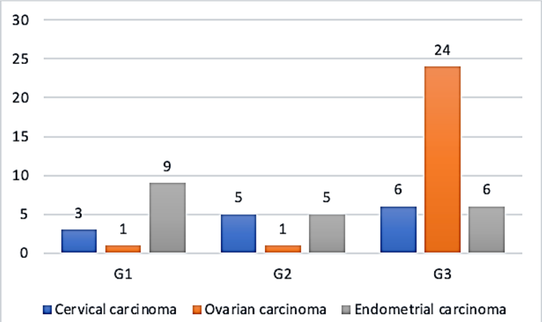

Figure 1: The relationship between gynecologic cancer type and tumor differentiation

The patients' and tumors' characteristics are listed in Table 1.

Table 1: Patient and tumor characteristics

	Age, year
Mean	60+/-9
Range	31-76
Type of cancer, nr.	
Cervical cancer	14
Ovarian cancer	26
Endometrial cancer	20
Tumor differentiation, nr.	
Well-differentiated cancer	13
Moderate differentiated cancer	11
Poorly differentiated cancer	36

The mean SULmax value for the entire group of patients was calculated as 7.83±5.73, with a mean SULmax value of 4.20±3.42 in the group of patients with well-differentiated cancer; 7.96±3.74 in the group with moderately differentiated cancer, and 8.40±6.28 in poorly differentiated cancer. There was a positive correlation between the measured SULmax, tumor differentiation, with higher glucose uptake in poorly differentiated cancer (Figure 2).

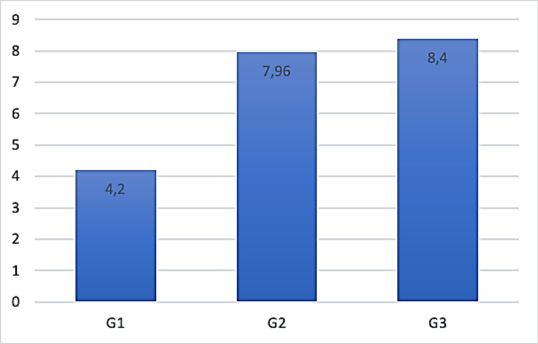

Figure 2: The relationship between glucose metabolism and tumor differentiation

When we analyzed the relationship between cancer type and SULmax, we found that endometrial cancer had the highest mean SULmax (8.36±6.75), followed by ovarian and cervical cancer.

Regardless of differentiation grade, endometrial cancer had the highest mean SULmax values in all differentiation grades. Among moderately differentiated tumors, cervical carcinoma showed higher values than ovarian carcinoma and lower values than endometrial carcinoma, and among poorly differentiated tumors, ovarian carcinoma showed higher values than cervical carcinoma and lower values than endometrial carcinoma (Figure 3).

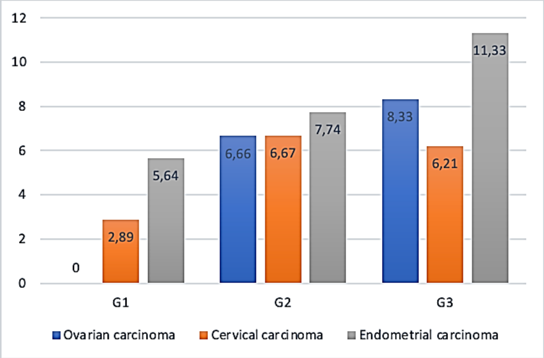

Figure 3: The relationship between glucose metabolism, type of malignancy, and tumor differentiation

The degree of tumor differentiation positively correlated with age, with patients diagnosed with G1 tumors having a mean age of 57±10 years, while patients with G3 tumors have a mean age of 62.7 ±9 years. We also found that glucose uptake was higher in patients older than 62 years.

DISCUSSION

In this study, we found that FDG uptake in primary tumor and secondary lesions varied according to cancer type and degree of differentiation. The SULmax value correlated with the degree of tumor differentiation in all gynecologic cancers.

Endometrial cancer had a significantly higher SULmax value than ovarian and cervical cancer for all tumor differentiation grades. Cervical cancer had higher values than ovarian cancer for moderately differentiated tumors, and for poorly differentiated tumors, the SULmax value was higher for ovarian cancer than for cervical cancer.

The current study also found that poorly differentiated tumors had a higher SULmax value than well- or moderately-differentiated tumors, with a significant difference in SULmax value for well- and poorly-differentiated tumors.

Similar results were obtained by Takagi et al. on a group of patients with endometrial carcinoma. They discovered that the level of glucose uptake significantly differs in patients with different grades of differentiation, being higher in those with G2 and G3. They also found that the degree of glucose uptake correlates with tumor size [11].

Another study that refers to the prognostic value of glucose uptake and its relationship with the degree of differentiation was conducted by Walentowicz-Sadlecka et al. The results demonstrated a progressive increase in glucose uptake as the degree of tumor differentiation advanced. Specifically, patients categorized as G1 exhibited lower uptake, while those in G2 and G3 displayed higher values. However, in their study, statistically significant differences between the three grades of differentiation were observed only in the case of patients classified in the G1 group compared to those in the G2 and G3 groups [12].

Kidd et al. show that tumor differentiation affects 18F-FDG uptake in cervical cancer. They found the same results regarding the correlation between FDG uptake and tumor differentiation as we did in our study. They also found that higher glucose uptake was correlated with an increased risk of lymph node metastasis in patients with cervical cancer [13,14].

More recently in patients with recurrent ovarian cancer, Jiang et al demonstrated that the level of glucose uptake in peritoneal lesions was a significant independent prognostic element [15].

On the other hand, in the study of patients with cervical cancer conducted by Mocciaro V et al, no correlation was found between the SULmax value and the degree of tumor differentiation [16].

The presence of conflicting results indicates that this is a complex area of research that requires prospective studies with a larger number of patients to evaluate the correlation between the parameters of PET and the histopathological features of gynecologic tumors.

Glucose uptake has also been associated with tumor aggressiveness in other cancers. Sachs S et al. reached similar results in a study of patients with lung cancer, showing that higher glucose uptake in the primary lesion was predictive of lymph node involvement and more aggressive tumor behavior [17]. Some authors also suggested that the correlation between FDG uptake in non-small cell lung cancer (NSCLC) and tumor proliferation may allow FDG-PET to serve as a non-invasive method for tumor grading. This is the case in the work published by Vesselle et al. in which tumor differentiation in NSCLC was found to correlate exactly with glucose uptake, with well-differentiated tumors having lower FDG uptake. [18].

As for the relationship between the age of patients at diagnosis and the aggressiveness of the cancer, expressed by the degree of tumor differentiation and SUVmax values, the results of our study suggest a positive correlation. These findings are also supported by studies conducted by Koual et al. and Gonzales-Rodilla et al. who described similar results when studying patients with endometrial cancer [19,20].

The current study provides some new insights into the relationship between gynecologic cancer, tumor differentiation, and glucose metabolism. We believe that the relationship between glucose uptake and the degree of tumor differentiation in gynecologic cancer could serve as a valuable prognostic tool and add to the existing clinical knowledge in this field.

Our study has some limitations – the relatively small number of patients and also the histologic type of malignancies, which included only carcinomas. As mentioned earlier, larger prospective studies are needed to validate glucose uptake, expressed as SUL values, as a prognostic marker in gynecologic malignancies.

CONCLUSIONS

In conclusion, the current study provides valuable insight into gynecologic cancer by correlating glucose uptake and the degree of tumor differentiation. The study also shows that glucose metabolism is highest in endometrial cancer, followed by ovarian and cervical cancer. In addition, the results show that glucose metabolism tends to increase with age. These findings contribute to our understanding of gynecologic cancer and highlight the importance of considering SULmax values and glucose metabolism as potential factors in disease evaluation and treatment.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research received no external funding.

Authors' contribution

R.M, D.C and P.M.S. planned the clinical study and contributed to the concept and design of the study. C.S, C.M., D.C., M. J and F.I. contributed to the data analysis and interpretation as well as to the translation and the critical revision of important intellectual content. T.M. and L.M. contributed to the writing of the manuscript and performed revision, language, and textual editing of the final version.

All authors contributed to the original draft preparation of the manuscript. All authors have read and agreed to the published version of the manuscript.

Patient consent for publication

Informed consent was obtained from all subjects involved in the study.

Ethics approval and consent to participate

All procedures performed in this paper were by the 1964 Helsinki Declaration and its later amendments or comparable ethical standards and according to the national ethical standards.

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers may cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor may not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Editor-in-Chief. The Editor-in-Chief reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at: http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

– Accessible to the public at no charge;

– Searchable by standard, electronic (Internet-based) methods;

– Open to all prospective registrants free of charge or at minimal cost;

– Validates registered information;

– Identifies trials with a unique number; and

– Includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, a target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The Journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 200 words. Abstracts for original articles should be formatted as detailed in the word form. Titles must not be longer than 120 characters (including spaces). In every article, there must be three to ten pertinent keywords specific to the article yet reasonably common within the subject discipline.

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article. This should be cited as Rom. J. Mil. Med. (year); (vol): [issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related “miniseries” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this

avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are suggested to limit to 3000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Executive Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate.

Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication, as presented at http://www.ICMJE.org/.

Spelling

The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units

All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations

Abbreviations should be used sparingly and only where they ease the reader's task by reducing the repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: the title page; the main text file according to the word model.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or an article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented according to the word model. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 200 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. If appropriate, divide the abstract with the headings: Background and Aim, Methods, Results, and Conclusions. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to ten keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser – http://www.nlm.nih.gov/mesh/meshhhome.html.

Text

Authors should use the word form in editing the submitted material.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square parentheses in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or fewer; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

Use Index Medicus as the style guide for references and other journal abbreviations.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table and legend must be

understandable without reference to the text. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, •, ‣ should be used (in that order) and *, **, *** should be reserved for P-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication:

Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com. A cover letter containing an authorship statement should be included. The cover letter should include a statement covering each of the following areas:

– Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author. It is not accepted the idea of equal contribution.

– Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.

– A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

– For research involving pharmacological agents, devices, or medical technology, a clear Conflict of Interest statement about any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

– For clinical trials, these have been registered in a publically accessible database (see more under ‘ETHICAL CONSIDERATIONS (Further Information)’ later in these guidelines).

If the above items are not included in the cover letter, manuscripts cannot be sent for review. Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section ‘Parts of the manuscript’, including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using the word model that is to be found on the web page (http://revistamedicinamilitara.ro/wpcontent/uploads/2022/07/Macheta-articole.docx).

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, high-resolution figures (at least 300 d.p.i.) saved as .eps, .jpg or .tif files are required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted Articles

Accepted Articles are published online after final acceptance, and appear in PDF format only.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing the proof of acceptance. It is therefore essential that a working e-mail address is provided for the corresponding author.

COPYRIGHT, LICENSING, AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is submitted.

Abstract: *This study investigates the influence of experience on stress responses and fine motor skills among professional male military parachutists. We analyzed 132 paratroopers, divided into a non-experienced group (NEG; ≤6 parachute jumps) and an experienced group (EG; >50 jumps). Baseline samples were collected 2.5 hours before participants performed a 500 m jump, with post-jump evaluations conducted immediately after landing. Results indicated that experience significantly influences fine motor skills and stress responses. Non-experienced jumpers showed greater degradation in fine motor skills and higher cortical arousal pre-jump levels, suggesting an increased anticipatory state. In contrast, experienced parachutists maintained more consistent fine motor skills and exhibited a ceiling effect in stress response. Leg strength was higher in non-experienced jumpers, reflecting youth and greater muscle mass, with no significant difference in hand strength. These findings highlight the role of experience in managing stress and maintaining motor skills under pressure. The study suggests further exploration into psychological aspects like motivation and resilience, along with the long-term effects of stress exposure. The importance of experience in high-stress military operations emphasizes the need for targeted training interventions to enhance stress-coping mechanisms in less experienced individuals.*

Keywords: *military parachutists; experience; stress response; fine motor skills; psychophysiological analysis*

INTRODUCTION

Fine motor skills are critical for various professionals, including athletes, and are notably influenced by an array of stressors, both psychological and physical [1]. Specifically, acute fatigue resulting from physical exertion can significantly impair these skills [1]. The impact of fatigue is modulated by several factors such as exhaustion, intensity, duration, and type of exercise, as well as the individual's experience level [2]. Traditionally, physiological explanations for the decline in fine motor skills due to fatigue have been focused on biochemical changes, such as the accumulation of hydrogen ions, inorganic phosphate, or ammonia [3]. These alterations adversely affect muscle contractility, hindering ATP-producing enzymes, disrupting the reuptake of calcium ions (Ca^{2+}), and leading to increased sarcoplasmic calcium concentrations [4]. Consequently, these physiological shifts can detrimentally affect the quality of neural connections and electrical activity, ultimately impairing fine motor coordination [3].

Supporting this concept, prior research has revealed notable impacts of physical exertion on motor and cognitive functions [5]. For example, soccer players exhibited a decrease in passing accuracy following a session of intense lower-body resistance training [3]. Similarly, cognitive functions like attention and reaction time were significantly impaired in individuals cycling at 70-100% of their maximum heart rate on an ergometer [6]. These findings underscore the complex interplay between physical activity, physiological stress, and fine motor skill performance, further elucidating the importance of understanding how different variables like exercise type, intensity, and individual training background influence these outcomes [7].

Further on, stress is a pivotal factor that can significantly affect fine motor skills, particularly in high-pressure environments such as the military [8]. The intense demands of military tasks often lead to brain overstimulation as soldiers must allocate extensive attentional resources to their surroundings and activities [9]. This overstimulation can result in concentration difficulties and distractions, shifting focus away from primary tasks and disrupting automatic motor execution [10]. Additionally, anxiety, a common response to the high-stress situations often encountered in military settings, can lead to reduced blood flow to the prefrontal cortex [2]. This reduction means less oxygen and nutrients reach the brain, thereby diminishing the effectiveness of executive functions [11]. Such impairments can negatively influence various brain regions, including the hippocampus, leading to issues with concentration, memory, decision-making, working memory, and ultimately, fine motor skills [11].

Moreover, in a military context, where decisions and actions often have critical consequences, the impact of stress and anxiety on fine motor skills becomes even more significant. Therefore, authors have noted that extreme social pressure, such as pre-competitive anxiety in military exercises or operations, exacerbates these effects [2,12-17]. On this line, both somatic and cognitive anxiety, often heightened in combat or high-intensity training scenarios, can impair motor skills. Furthermore, environmental factors typical in military settings, like exposure to loud noises exceeding 89 dB, can also contribute to the decline in fine motor skills [18]. These factors, combined with the need for precise and coordinated movements in various military operations, underline the importance of understanding and mitigating the effects of stress and anxiety on motor performance in military personnel [18]. Addressing these challenges through training, mental health support, and adaptive strategies can enhance the overall effectiveness and safety of soldiers in demanding operational environments [19].

In addition, the psychophysiological stress response and its modulation by experience is a critical area of study, particularly relevant in high-stakes environments such as medicine, the military, and sports. It has been demonstrated that experience plays a pivotal role in this modulation [20]. For example, studies show that the stress response of novice paratroopers after a low-altitude jump is significantly more pronounced compared to their experienced counterparts [21]. This difference highlights how experience directly influences the psychophysiological reaction to stress, an essential consideration for learning and performing under pressure [21-23]. The presence of stress hormones like cortisol, glucocorticoids, and corticotropin can impair the central nervous system and higher cognitive processes, affecting overall performance [22,23]. Skilled and experienced individuals, therefore, might exhibit optimal motor performance due to a more selectively tuned stress response, coupled with potentially enhanced cognitive automation and executive function efficiency under stress [21,24,25].

However, the intricate relationship between experience in stressful contexts and fine motor skills remains not fully elucidated. This uncertainty underscores the objective of our current research, which is to analyze the impact of experience on the psychophysiological response and fine motor skills under intense stress. We hypothesize that: i) non-experienced participants will show a more substantial negative effect on fine motor skills compared to their experienced counterparts, and ii) higher cortical arousal states and self-confidence, along with lower levels of cognitive and somatic anxiety, will be positively correlated with enhanced fine motor skills. This investigation aims to provide a deeper insight into how experience shapes our physiological and psychological responses in stress-filled scenarios, offering critical implications for training and performance optimization in various high-pressure fields.

MATERIALS AND METHODS

Participants

In this study, we conducted a comprehensive analysis of 132 male professional paratroopers, meticulously categorized into two distinct cohorts: i) the Non-Experienced Group (NEG), comprising younger members (mean age: 23.2 ± 2.3 years, ≤ 6 parachute jumps) primarily recruited from the first-year cohort of the air academy; and ii) the Experienced Group (EG), consisting of significantly seasoned practitioners (mean age: 34.8 ± 4.0 years, > 50 parachute jumps), each boasting over five years of dedicated service within the unit. We applied stringent exclusion criteria to both groups, disqualifying individuals presenting any medical or physical conditions potentially hindering participation or firearms usage, such as cardiovascular diseases, as well as those currently using dietary supplements, stimulants, or any other ergogenic aids.

Participants from both groups were uniformly outfitted in standard-issue military attire, which included boots, helmets, tactical fighting load carriers, body armor, and an HK G-36 rifle. Additionally, each individual was equipped with regulatory emergency parachutes for the execution of the jump. The total gear weight amounted to approximately 39.3 kilograms. Before their involvement, detailed explanations of the experimental procedures were provided to all participants, from whom voluntary written informed consent was subsequently obtained.

It is crucial to note that the entire study adhered rigorously to the ethical standards outlined in the Helsinki Declaration (as revised in Brazil, 2013). The research protocol received the necessary approval from the University's ethical committee, ensuring the highest standards of research integrity and participant welfare.

Procedure

To comprehensively address the objectives of our study, we conducted a detailed investigation into the physiological and psychological responses of both non-experienced and experienced paratroopers before and after performing a parachute jump.

Baseline data were meticulously collected 2 hours and 30 minutes before the embarkation, ensuring a robust understanding of the participants' initial state.

The participants boarded a Hercules T-21 aircraft for the jump, which was executed from an altitude of 500 meters. In this structured activity, the parachute deployment was automatic, triggered immediately upon exiting the aircraft. This process ensured a standardized jumping experience for all participants, crucial for the reliability of our data.

Following the descent and immediate landing, participants were swiftly escorted to a specially equipped field laboratory situated near the landing site. This arrangement was critical to capture the immediate post-jump physiological and psychological responses with minimal delay or external influence, thereby preserving the integrity and immediacy of the data.

In the field laboratory, a comprehensive post-jump evaluation was conducted, encompassing a series of assessments designed to measure the effects of the jump on various fine motor skills, cognitive functions, and stress responses. This timely assessment was vital to understanding the acute impact of parachuting on these key variables in both inexperienced and seasoned military personnel.

Materials

Before and after the automatic parachute jump the following parameters were analyzed according to previous authors [21]:

Psychophysiological parameters

Lower body muscular strength manifestation using a vertical jump test. We used the Sensorize FreePowerJump system (SANRO Electromedicina, Madrid. Spain) which recorded flight time (s) and jump height (cm) to evaluate the Squat Jump (SJ). Three attempts were recorded, and only the best attempt was considered.

Isometric hand-grip strength

It was measured using a TKK 5402 dynamometer (Takei Scientific Instruments CO. LTD)

Each participant's grip strength was measured on the shooting hand while standing with 0 degrees of shoulder flexion, 90 degrees of elbow flexion, and the forearm in neutral. Idem, was done pre-post and among series.

Cortical arousal by the critical flicker fusion threshold (CFFT)

An increase in CFFT suggests an increase in cortical arousal and information process, by contrast, when the values fall below the baseline, it suggests a reduction in the efficiency of processing information and fatigue of the central nervous system [26]. Subjects were seated in front of a viewing chamber (Lafayette Instrument Flicker Fusion Control Unit Model 12021), which was constructed to control extraneous factors that might distort CFFT values. Two light-emitting diodes (58 cd/m^2) were presented simultaneously in the viewing chamber, one for the left eye and one for the right eye. The stimuli were separated by 2.75 cm (center to center) with a stimulus-to-eye distance of 15 cm and a viewing angle of 1.9°. The inside of the viewing chamber is painted flat black to minimize reflection. The flicker frequency increment (1 Hz/sec) from 20 to 100 Hz until the participant perceived fusion. After a fovea binocular fixation, participants were required to respond by pressing a button upon identifying the visual fusion thresholds. Before the experiment, they performed as many practice trials as needed to become familiarized with the exigencies of the CFF test. Then, five trials were performed with an interval of 5 seconds. In each one of the tests, time was quantified as the amount of time that a subject took to detect the changes in the lights from the beginning of the test until the moment of pressing a button. The average of these times was calculated to determine the CFFT [15,27,28]

Cognitive Anxiety (CA), Self Confidence (SC), and Somatic Anxiety (SA)

Those parameters were evaluated using the CSAI-2R [29]. In this questionnaire, 17 items are evaluated: 5 items for CA, 7 items for SA, and 5 items for SC, respectively. The response scale evaluated the intensity of each symptom on a scale from 1 (not at all) to 4 (very much). Higher scores on cognitive and somatic anxiety indicated a higher level of anxiety, as well as higher scores on the self-confidence scale, indicated a higher level of self-confidence.

Fine motor skills were evaluated through the time of re-loading a 15 bullet of 9 mm caliber into a Beretta pistol magazine since previous authors used the same protocol to analyze specific fine motor skills for the population used in the present research [30–32].

Statistical analysis

Data were analyzed using the Statistical Package for the Social Sciences (SPSS) version 22.0 (SPSS Inc., Chicago, Ill., USA). Means and SDs were calculated using traditional statistical techniques. Normality was tested with the Kolmogorov-Smirnov test. A one-factor ANOVA for intergroup comparisons (i.e. pre and post-test differences; change score (Δ) differences) and a Student's T-test for intragroup comparisons were conducted. The Effect Size was tested by Cohen's D. Pearson correlation coefficient was calculated, and separate multiple regression analysis using the Forward method was performed to determine the presence of predictor variables on the cortical arousal and the fine motor performance. In all these analyses, the significance level was set at $p \leq 0.05$.

RESULTS

The analysis of psychophysiological and fine motor skills in non-experienced and experienced paratroopers before and after a jump revealed some key insights (Table 1). Both groups demonstrated significant improvements in Squat Jump performance, indicating enhanced lower-body muscular strength, likely influenced by the acute stress or adrenaline rush associated with the jump. Notably, this improvement was more pronounced in non-experienced jumpers. In terms of Isometric Hand Strength, there was a stable performance in the non-experienced group, while the experienced group showed a slight but significant decrease post-jump. This outcome might suggest a more nuanced impact of experience on the regulation of grip strength under stress. Critical Flicker Fusion Threshold results indicated an increase in both groups, with the experienced group showing a significant improvement. This finding implies an enhanced capacity for cortical arousal and information processing, especially among the experienced paratroopers.

Regarding fine motor skills, measured through Pistol Magazine Reload Time, there was a significant improvement in the non-experienced group but no change in the experienced group. This difference highlights the possible influence of prior experience on maintaining consistent performance under stress.

Cognitive and Somatic Anxiety levels decreased in both groups, with a notable reduction in physical symptoms of anxiety post-jump across both groups. Interestingly, while Self-Confidence remained unchanged in non-experienced paratroopers, it significantly increased among the experienced ones after the jump, suggesting a boost in self-assurance likely stemming from their familiarity and proficiency in such high-stress scenarios.

Overall, these results underscore the significant effects of experience in shaping the psychophysiological and fine motor skills responses of paratroopers to stress. While certain responses like improvements in muscular strength and reductions in anxiety seem universal to both groups, aspects like grip strength regulation, cortical arousal, fine motor skills, and self-confidence exhibit distinct patterns, emphasizing the nuanced impact of experience in high-stress military operations.

Table 1: Modifications of study variables in non-experienced and experienced participants

Variable	Non-experienced					Experienced				
	Pre	Post	t	p	Effect Size	Pre	Post	t	p	Effect Size

SC	15.2±2.6	15.6±5.1	-0.697	0.489	0.15	18.6±1.7 (0.037)	19.3±1.2 (0.020)	-4.155	0.000	0.41

Between parenthesis p values lower than 0.05 between novel and veterans' paratroopers. Squat Jump (SJ), Isometric Hand Strength (IHS), Critical Flicker Fusion Threshold (CFFT), Pistol Magazine Reload Time (PMRT), Cognitive Anxiety (CA), Somatic Anxiety (SA) and Self-Confidence (SC).

In Table 2, the results of a one-factor ANOVA analysis on various psychophysiological and performance variables are presented, shedding light on the impact of an unstated factor (likely experience or a specific training intervention) on these variables. Data suggests that whatever factor was being analyzed (experience, training, or another intervention) had a pronounced and often significant effect on physical abilities (like SJ and PMTR), cognitive function (as in CFFT), and psychological states (CA, SA, and SC). The lack of significant changes in some deltas might indicate that while the factor made a significant initial impact, its effect on the rate of change over time was not always strong, possibly due to a ceiling effect, adaptation over time, or other intervening variables (Table 3 and Table 4). The strong influence of age also suggests that demographic factors can be crucial in how individuals respond to training, experience, or other interventions in these domains.

Table 2: Results of the variables analyzed in the one-factor ANOVA

Variable	F	P	Variable	F	P

Table 4 shows the correlations between changes in fine motor performance and various psychophysiological parameters. Significant findings include positive correlations of changes in fine motor performance with age and records of jumps, suggesting that improvements in fine motor skills are associated with older age and more jumping records. A negative correlation is observed with pre-test vertical jump performance, indicating that better initial physical performance might relate to lesser improvements in motor skills. Furthermore, there is a strong negative correlation with pre-test fine motor performance, suggesting that higher initial skill levels might see smaller subsequent improvements. Furthermore, negative correlations of changes in fine motor performance with cognitive and somatic anxiety post-test, and a positive correlation with self-confidence pre-test were also seen.

DISCUSSION

Authors should discuss the results and how they can be interpreted from the perspective of previous studies and the working hypotheses. The findings and their implications should be discussed in the broadest context possible.

Future research directions may also be highlighted. The present research aimed to analyze the effect of experience on the psychophysiological response and fine motor skills in a highly stressful situation. Hypothesis i. was partially supported, as non-experienced participants demonstrated a more pronounced decline in fine motor skills compared to their experienced counterparts. This outcome underscores the impact of experience in managing the physiological and psychological stressors affecting motor skill performance. For hypothesis ii., the findings revealed a nuanced relationship between psychophysiological responses and fine motor skills. While greater cortical arousal and self-confidence, as well as lower levels of cognitive and somatic anxiety, generally correlated with enhanced fine motor skills, these associations were more complex than initially hypothesized. Experienced participants displayed better stress management and resilience, leading to superior fine motor skill execution under pressure. However, this relationship was not strictly linear and suggests the influence of additional moderating factors, such as individual stress tolerance, coping mechanisms, and task-specific training. These results highlight the multifaceted nature of psychophysiological responses in high-stress scenarios and their differential impact on fine motor skill performance based on an individual's experience level.

On this line, the data analysis revealed an intriguing pattern: experienced participants exhibited an increase in Critical Flicker Fusion Threshold (CFFT) following their jumps, suggesting heightened cortical demands imposed by this complex and perilous task. Notably, before the jump, non-experienced participants displayed significantly higher CFFT compared to their experienced counterparts. This unexpected finding could be attributed to an increased level of cortical hyperactivation. While previous studies have identified sympathoadrenal hyperactivation in similar contexts [2,20,33], our results indicate a concurrent elevation in cortical arousal. This heightened state in non-experienced participants may be a preparatory response to the novel and challenging situation, potentially facilitating mental anticipation of potential hazards and the formulation of strategies to address them. This phenomenon also includes a thorough mental review of the jump procedures. Similar patterns of elevated cortical arousal in novice participants have been reported in military personnel engaged in ground operations [2,34], lending support to our observations. Conversely, the lower cortical arousal observed in experienced paratroopers may indicate a tendency to rely on ingrained standard operating procedures, honed through extensive training and requiring lesser cognitive exertion. This strategy, as suggested by prior research, likely optimizes performance by conserving cognitive resources, allowing for a more efficient and focused execution of well-practiced tasks.

Following the parachute jump, participants exhibited an increase in leg strength, a phenomenon previously linked to enhanced sympathetic modulation triggered by the body's fight-or-flight response system [30,35]. However, in this instance, the significant muscular demand on the leg muscles, due to the impact of landing, may also explain this strength augmentation. Conversely, no significant changes were observed in isometric hand strength post-jump, possibly reflecting the less intense muscular engagement required by these muscles during an automatic parachute jump. Yet, notable differences emerged between experienced and non-experienced participants: non-experienced paratroopers showed higher leg strength, but lower hand strength compared to their experienced counterparts. This variation in major muscle groups like the legs might be attributable to the generally greater muscle mass in the younger, non-experienced group [36], though this factor appears less relevant in smaller muscle groups such as the hands.

From a psychological standpoint, experienced paratroopers reported lower levels of anxiety compared to their non-experienced peers, aligning with findings from prior studies involving similar demographic groups [37]. Interestingly, we noted a reduction in somatic anxiety among non-experienced participants post-jump, a shift potentially linked to the alleviation of immediate stress following the completion of the parachute jump. This differential response highlights the nuanced interplay between physical exertion, psychological stress, and experience in high-stress environments like military parachute jumping [31].

Furthermore, the established negative impact of anxiety on fine motor skills has been well documented in previous research [38]. In this context, it was anticipated that the anxiety reduction observed in non-experienced jumpers, despite their significant anticipatory anxiety response, would enhance their performance in fine motor skills tasks. Correspondingly, improvements were seen in Pistol Maga-zine

Reload Time (PMTR) among non-experienced jumpers, which might also be linked to the sustained physiological arousal following the jump [32]. In contrast, experienced paratroopers exhibited no notable differences in PMTR before and after the jump, a phenomenon potentially explained by a performance ceiling effect. In such a highly skilled group, PMTR appears to be minimally affected by the stress and excitement inherent in a parachute jump. This outcome suggests an optimal level of coping in challenging scenarios, a trait similarly observed in seasoned military parachute jumpers [39]. Indeed, a strong correlation has been established between Isometric Hand Strength (IHS) and better performance in both PMTR and shooting tasks [40]. This finding is consistent with the observations that experienced paratroopers displayed superior IHS and PMTR at both pre-jump and post-jump measurements. Their advanced skills and training may facilitate a more consistent and effective engagement in tasks requiring fine motor control, underscoring the significant advantage conferred by experience and expertise in military operations.

Finally, regarding the correlational analysis, data suggest that the interplay between psychophysiological states and fine motor skills is complex, particularly under high-stress conditions. Significant correlations were found between fine motor skills and various psychophysiological parameters, including arousal and anxiety, suggesting a relationship that is more intricate than the traditional perspectives on stress and performance. Indeed, there seems to be a nuanced connection between the level of initial cortical arousal, its changes over time, and motor skill performance. In this vein, studies have supported this assertion, indicating that higher levels of initial cortical arousal correlated positively with enhanced performance in precision tasks under pressure. For instance, in archery, an optimal level of initial arousal was found conducive to increased focus and steadier hand movements, thereby improving accuracy [41]. Similarly, studies on musicians revealed that those with lower initial levels of stress and anxiety, and who exhibited smaller physiological arousal changes during performances, tended to maintain better motor control, thus delivering superior performance. These findings corroborate our data and underscore the idea that managing arousal levels can be crucial in fine motor skill activities where precision and control are paramount [42]. Nonetheless, it has been proposed that the straightforward interpretation of the arousal-performance relationship must also consider factors such as task complexity, individual stress tolerance, and prior training [43].

Furthermore, research indicates that variables like age and self-confidence significantly influence fine motor performance under stress. These insights are in line with studies demonstrating that older individuals often excel in high-pressure medical scenarios, likely benefiting from their life experiences and heightened self-confidence [44]. Similarly, police officers with greater self-confidence have been observed to exhibit superior performance in stress-induced precision tasks [45].

Therefore, acknowledging these multifaceted influences underscores the necessity for bespoke training and stress management strategies. Such recognition heralds a pivotal shift towards more personalized approaches in performance training and preparation for high-stress environments. This paradigm shift not only reflects an evolving understanding of stress and performance dynamics but also emphasizes the importance of individual differences, advocating for more nuanced and effective training methods that cater to these variances.

Limitations of the study

One limitation of this study is its focus solely on male professional parachutists, restricting the generalizability of findings to other populations, including females and amateur or non-military parachutists. The specific stressor — military parachuting — may elicit unique psychophysiological responses, different from those induced by other stressors in various professional or athletic settings. Additionally, the measurement of fine motor skills and stress responses was confined to specific methods and tools, which might not capture all nuances of these complex phenomena. Future studies should consider a broader, more diverse participant base and a wider range of stressors and assessment techniques.

Practical applications

Our research on the effects of experience on psychophysiological responses and fine motor skills, with a focus on military parachutists, reveals critical insights with broad practical applications, particularly for high-stress professions. We discern that targeted interventions could markedly improve stress management and fine motor skills in less experienced individuals. In this line, simulation-based training stands out as an influential tool, offering a realistic, yet controlled, platform for developing crucial skills and adapting to stress. The use of VR and AR in simulations could provide immersive, risk-free environments for practitioners to build experience and confidence. This technique not only enhances skill acquisition but also allows individuals to mentally prepare for the high-stress scenarios they will face. Moreover, mindfulness and cognitive training programs, targeting attention control, emotional regulation, and mental resilience, present another viable strategy. These programs could help mitigate stress effects, enhance decision-making, and maintain fine motor control during high-pressure situations. Particularly, mindfulness exercises can reduce the psychophysiological impacts of stress, leading to improved performance.

Furthermore, physical conditioning specific to the professional demands also plays a key role. Appropriate fitness training can alleviate physiological stress responses, indirectly benefiting cognitive functions and fine motor skills. Regular psychological assessments can identify individual stress and anxiety responses, enabling more personalized training approaches. Building resilience, managing anxiety, and learning effective stress coping mechanisms are crucial in these trainings. In addition, neurofeedback and biofeedback techniques offer innovative methods for monitoring and controlling physiological stress responses. For example, controlling heart rate variability might be an effective way to manage anxiety and bolster focus in tense environments. Also, training that emphasizes team dynamics and communication is particularly valuable where teamwork is crucial under stress. Effective team interactions can significantly lessen individual stress levels and elevate collective performance.

Therefore, implementing these strategies not only aims to boost individual performance in stressful settings but also contributes to long-term well-being, professional durability, and the efficiency of teams in such environments. For less experienced individuals, these interventions can be crucial in bridging the experience gap, enhancing their capacity to manage stress, and improving their fine motor skills, ultimately leading to better overall performance and adaptability in their respective high-stress professions.

Future research lines

Considering the intricate connections between psycho-physiological responses and fine motor skills as observed in military parachutists, future research avenues appear both extensive and varied. Investigating these dynamics across different high-stress professions and sports could offer a broader understanding of how distinct stress levels influence fine motor skills in contexts such as surgery, law enforcement, or competitive disciplines like archery. Longitudinal studies focusing on the long-term impact of chronic stress exposure could unveil critical insights into the effects on mental health, well-being, and the maintenance of fine motor skills, highlighting the need for proactive intervention strategies. Further exploration into psychological factors beyond anxiety, including resilience, motivation, and risk perception, would enrich our comprehension of their roles in performance under stress. There's also a pressing need to develop and evaluate intervention strategies and training programs, including mindfulness, cognitive-behavioral approaches, and simulated environments, aimed particularly at enhancing the skills and stress management capabilities of the less experienced. Assessing the efficacy of simulator training in preparing individuals for high-stress scenarios, understanding the influence of physical fitness on stress response, and integrating neuroimaging and physiological monitoring to decrypt the brain-body interactions during stress, could provide transformative insights. Furthermore, exploring genetic and biochemical markers like cortisol levels might lead to more tailored training and development protocols. Lastly, cross-cultural studies would offer a valuable perspective on how cultural variations impact stress perception and coping mechanisms, potentially guiding global strategies in stress management and skill enhancement. This wide-ranging research agenda underscores the complexity of stress and performance, especially in high-stakes, high-stress environments, promising not only to deepen our understanding but also to significantly improve training and support for professionals in such challenging roles.

CONCLUSIONS

This study's exploration into the effects of experience on psychophysiological responses and fine motor skills in military parachutists underscores the intricate relationship between stress, experience, and motor performance. Notably, experienced parachutists displayed superior motor skills and lower stress responses, likely attributed to their habitual exposure to high-stress environments and refined coping mechanisms. Contrarily, non-experienced individuals showed heightened stress markers and impacted motor skills, although some improvement in performance post-exposure suggests potential adaptability. These findings illuminate the importance of experience in moderating stress and enhancing motor proficiency. They also highlight the need for tailored training programs, especially for novices, focusing on stress management, skill acquisition, and psychological resilience to bridge the experience gap. This research contributes valuable insights into stress-induced motor skill impairment, suggesting that experience plays a crucial role in optimally managing high-stress situations essential in military and other high-risk professions.

Abstract: *Background: Head and neck cancers, and particularly, oral cancers have a complex pathogenesis that includes genetic mutations and epigenetic alterations which interfere with cellular signaling and can trigger tumor development. The purpose of this study was to reveal whether low-frequency hotspot mutations may be detected in a study lot with histopathological evidence of squamous cell carcinoma (SCC) of the oral mucosa and skin of the head and neck. Methods: Tumor biopsies from treatment-naïve patients were tested for BRAF V600, NRAS G12/G13, NRAS Q61, KRAS Q61 mutations, and EGFR exon 19 deletions (Ex19Del) using droplet digital PCR (ddPCR). The tumors were also analyzed for EGFR T790M mutations by RT-PCR, using a CE-IVD validated kit, with a limit of detection of 0.05%. Results: None of the examined cases exhibited NRAS G12/G13, NRAS Q61, KRAS Q61, BRAF V600, or EGFR T790M mutations, indicating that these alterations are rare events in SCC pathogenesis. Interestingly, among the 12 specimens tested by ddPCR for EGFR Ex19Del, an HPV-negative cSCC tumor occurring in the parotid region tested positive for this drug-sensitizing mutation, offering unexplored therapeutic perspectives to the patient from whom it was collected. Conclusions: Our study highlights the important clinical implications of detecting low-frequency hotspot mutations in tumor biopsies by ddPCR. We believe that the ddPCR-assisted analysis of these mutations in larger SCC cohorts may provide us with mechanistic insights regarding their role in SCC pathogenesis and guide the development of novel therapeutic strategies for this problematic disease.*

Keywords: *head and neck squamous cell carcinoma; droplet digital PCR (ddPCR); targeted therapy, immunotherapy*

INTRODUCTION

Squamous cell carcinomas (SCCs) are one of the most unpredictable and widespread neoplasms globally, presenting a significant socio-economic burden on healthcare systems worldwide [1]. SCC development has been linked to the dysregulation of several molecules involved in different stages of squamous lineage commitment and keratinocyte terminal differentiation [2]. However, the exact identity and the precise order of the genetic and epigenetic alterations facilitating keratinocyte malignant transformation remain elusive. Several research groups postulated that epidermal clones with mutated p53 may be at the origin of SCC, as they lead to squamous dysplasia and in situ SCC, which subsequently progress to metastatic SCC [3]. At the same time, emerging evidence suggests that the disruption of the mitogen-activated protein kinase (MAPK) signaling pathway, activated by epidermal growth factor receptor (EGFR), facilitates the development and progression of various malignancies, including head and neck squamous cell carcinoma (HNSCC) and cutaneous SCC (cSCC) [3,4]. The MAPK pathway may be depicted as a complex regulatory network that links the tumor microenvironment with the cell nucleus, converting the extracellular signals into intracellular responses such as cell proliferation, differentiation, or apoptosis [4,5]. RAFs (A-/B-/C-RAF), RASs (N-/H-/K-RAS), MEKs, and MAPKs kinases are the most notorious constituents of the MAPK signaling pathway, behaving as powerful oncogenes in various human cancers. Thus, any alteration within those signaling components may lead to apoptosis resistance and uncontrolled cellular growth [4]. Beyond the critical role of EGFR/MAPK signaling in HNSCC development, the various nodal points within the signaling pathway can be converted into therapeutic vulnerabilities in these neoplasms. For instance, BRAF V600E-mutant ameloblastomas may be targeted with BRAF inhibitors such as vemurafenib and dabrafenib, whereas HRAS-mutant HNSCC can be approached with farnesyltransferase inhibitors (FTis) like tipifarnib [4,6]. Despite these recent discoveries, the main therapeutic approach for HNSCC and cSCC combines surgery with radiation therapy and systemic chemotherapy, with ancillary reconstructions depending on case complexity and structures involved [7–9]. Surgical excision of the tumor mass remains the cornerstone of treatment for resectable SCC, followed by adjuvant radiotherapy, with or without chemotherapy [10,11]. The tumoral resection may carry additional risks when considering local infiltration, anatomical variants, or surgical approach [12–14].

The stratified epithelium from which SCC originates can be found distributed on the surface of the outer integument or covering organs and cavities such as the oral cavity, sinonasal cavity, oropharynx, larynx, esophagus, lung, and anogenital region [15]. SCCs are currently classified and examined taking into account the anatomical divisions of the human body; therefore, the SCCs of the head and neck are treated differently from those of the lung [2]. Here, we will focus exclusively on SCCs of the skin and of the mucosal epithelium of the oral cavity and lips (OSCC). Although both tumor types arise from the disruption of the same differentiation programs, cSCC and OSCC are considered distinct entities with different risk factors [16,17]. The main etiological factors for OSCC include tobacco and alcohol usage, and human papillomavirus (HPV) infection [15,18,19]. For cSCC and lower lip SCC, the most prominent risk factor remains increased exposure to ultraviolet radiation (UVR), followed by a personal history of skin cancer and HPV infection [19,20].

cSCC is the second most common cancer worldwide, and its incidence is steadily increasing in the Caucasian population. As cSCC is often invasive, inaesthetic, and locally destructive, such diagnosis usually involves complex skin surgeries and facial reconstructions [21]. While the majority of cSCC patients present with a very good prognosis, 1.5-5.2% of cases may develop life-threatening metastases [22,23]. Moreover, owing to the high incidence rates, in the United States, the mortality rate associated with cSCC is comparable to that reported for more aggressive tumors such as leukemia and melanoma [22]. The number of cSCC-associated deaths is hence expected to surpass that of melanoma in the next 5 years, mainly due to the rise in HPV infections [24]. HNSCC, the sixth most common type of cancer globally, represented mainly by OSCC, also exhibits a poor overall survival (OS) rate. Despite advancements in diagnostic and treatment methods, the HNSCC 5-year OS rate remains approximately 50% [25], suggesting that more intensive scientific efforts should be devoted to understanding the complex biology of HNSCC tumors. Molecular studies to identify the key factors driving cSCC and OSCC development are ongoing, aiming to identify the most promising diagnostic biomarkers and therapeutic targets for these problematic diseases [5,26,27].

The latest advancements in omics technologies facilitated the identification of several hotspot mutations in the EGFR/MAPK signaling pathway which have been harnessed for targeted pharmacological interventions in cancer patients. For instance, the observation that 80% of HNSCCs exhibit EGFR overexpression led to the development and subsequent approval by the Food and Drug Administration (FDA) of Cetuximab, an anti-EGFR monoclonal antibody, to be used in combination with radiotherapy in locally advanced HNSCC [28]. Yet, the dissection of the mutational spectrum of the EGFR gene served as a foundation for the development and implementation of novel EGFR-targeted therapies in clinical settings. For instance, genetic alterations such as exon 19 deletions (Ex19Del) and exon 21 substitutions (e.g., L858R), representing the most common EGFR mutations in non-small cell lung cancer (NSCLC), confer sensitivity to first (gefitinib and erlotinib) and second-generation (nilotinib, dasatinib) tyrosine kinase inhibitors (TKIs) [29]. In addition, exon 20 substitutions which include EGFR T790M mutations and are generally associated with NSCLC resistance to first-generation TKIs, may be also matched with targeted therapy in cancer patients, particularly with third-generation TKIs such as osimertinib and alflutinib [29]. In HNSCC/cSCC clinical cohorts, single-target TKIs, such as gefitinib and erlotinib were shown to improve modestly patient survival rates when given as monotherapy [30]. However, promising results have been reported when small TKIs were combined with other agents such as pembrolizumab, cisplatin, or docetaxel, in recurrent and metastatic settings [31]. This suggests that EGFR mutations may be exploited for targeted therapeutic interventions in the future, once the clinicians validate the most beneficial drug combinations. Alternative strategies for tailored therapy in HNSCC include a) FTIs, such as tipifarnib, for HRAS-mutant HNSCC (recently FDA-approved); b) cetuximab for SCC presenting with KRAS germline variants; c) EGFR inhibitors for HNSCC tumors harboring MAPK1 mutations; d) BRAFi and

MEKi for BRAF V600E-mutant ameloblastomas, combined or not with immunotherapies [4].

As we described earlier, the genetic assessment of BRAF, a serine/threonine protein kinase mutated in 60% of cutaneous melanomas and more than 15% of human cancers, may also expand the anti-cancer armamentarium in cSCC/HNSCC [32]. Despite the low prevalence of BRAF mutations in SCC of the head and neck (2%), HNSCC patients carrying these alterations present with improved clinical outcomes after BRAF and MEK inhibition [33]. RAS is another key oncogene in the pathogenesis of human cancers. KRAS mutations were identified in 2.89% of HNSCC cases, most frequently in tumors with sinonasal localization, whereas NRAS alterations were reported in 2.2% of cases, especially in tumors of the nasopharynx [34]. A recent meta-analysis highlights that oncogenic KRAS may be associated with significantly enhanced immune checkpoint molecule (ICM) expression and immune evasion programs within the tumor microenvironment, making KRAS-mutant tumors promising candidates for immune checkpoint inhibition (ICI) in the clinical setting [35]. However, several recent reports highlight that the MAPK-mutant status may serve as an indicator of a favorable response to immunotherapy in HNSCC, mainly due to the increased CD8+ T cell and dendritic cell infiltrations reported within these tumors, representative of an active cytolytic CD8+T-inflamed status [36].

The present study aims to explore the role and prevalence of KRAS, NRAS, BRAF, and EGFR mutations in a pilot group of patients diagnosed with SCC of the oral mucosa and skin.

MATERIALS AND METHODS

Patients and samples

Twelve patients diagnosed with squamous cell neoplasms of the head and neck between February 2017 and October 2019 were included in the present study. Three patients presented with cSCC, whereas nine had OSCC. Archived formalin-fixed paraffin-embedded (FFPE) tissues from these 12 subjects were obtained from the Department of Oral and Maxillofacial Surgery of the Carol Davila Military Emergency Hospital in Bucharest, Romania. All participants provided written informed consent to take part in this study. Ethical approval for this retrospective analysis was obtained from the Ethics Committee of the Carol Davila Central Military Emergency Hospital. The study including all procedures and handling of patients' samples was carried out in accordance with the guidelines of the Declaration of Helsinki and national as well as institutional guidelines for research ethics. The clinical and histopathological characteristics of the SCC tumors were analyzed following the latest version of the international standard American Joint Committee on Cancer (AJCC) tumor/ node/metastasis (TNM) system for the classification and staging of tumors. Presence of the EGFR T790M mutation was analyzed with the gb ONCO EGFR (T790M) Real-Time PCR assay (PN: 3245-048, Generi Biotech, Czech Republic); additional mutations in the EGFR-RAS-RAF mutations were tested using the droplet digital PCR (ddPCR) Screening assays for BRAF V600 (PN: 12001037), NRAS G12/G13 (PN: 12001627), NRAS Q61 (PN: 12001006), KRAS Q61 (PN: 12001626) mutations and EGFR exon 19 deletions (PN: 12002392) (all BioRad, Hercules, USA); details of these techniques are outlined below.

DNA extraction

The total genomic DNA was extracted from FFPE tissues (3 x 15-μM-thick sections) using the ReliaPrep™ FFPE gDNA Miniprep kit (PN: A2352, Promega). The protocol includes a proprietary deparaffinization method that does not rely on the use of xylene or any other hazardous solvents, ensuring at the same time the extraction of high-purity nucleic acids from FFPE samples. Following the deparaffinization of the FFPE tissue sections, the extraction protocol involves the lysis of the tissues. Nucleic acids released from the cells are further bound on the surface of a spin filter membrane and eluted in 50 μL of elution buffer after several rounds of washing. The purified genomic DNA was kept on ice and quantified using a Nanodrop spectrophotometer.

Droplet digital PCR

Before carrying out the ddPCR reaction, the genomic DNA samples were subjected to uracil-DNA-glycosylase treatment (UDG; PN: 1B1634, VWR) following the manufacturer's instructions. This step aimed to eliminate potential C>T transitions that could arise from tissue fixation, therefore reducing the risk of false-positive ddPCR reactions. All gDNA samples were analyzed in triplicate.

The ddPCR mixture requires the addition of 10 μL of 2x ddPCR Supermix for Probes (no dUTP) per reaction. The 2x ddPCR Supermix is a proprietary reagent containing an optimized reaction mix for primers and probes. Additionally, 1 μL of 20x BRAF (NRAS/KRAS/EGFR) primer and 3 μL of UDG-treated gDNA (7 ng/μL) were included in each ddPCR reaction, and the final reaction volume was adjusted to 20 μL by adding an appropriate volume of RNase/DNase-free water. Each analytical run included negative (wild-type control, WT) and positive controls at the same concentration as the analyzed gDNA samples. The positive controls were provided by Horizon Discovery (PN: HD701) and contained recurrent mutations in BRAF, KRAS, NRAS, cKIT, EGFR, and PIK3CA genes, at allelic frequencies ranging from 1% to 24.5%. The negative controls were WT genomic DNA samples acquired from Promega

Corporation (PN: G1471).

In the droplet generation step, individual reaction mixtures were loaded into disposable DG8 cartridges (Bio-Rad) along with 70 µL of droplet generation oil and passed through the microfluidic channels of a droplet generator. The resulting droplets from each well were transferred into a 96-well PCR plate, heat-sealed, and subjected to the following PCR conditions: 95°C for 10 min, followed by 40 cycles of 94°C for 30 s, 60°C for 1 min, and 98°C for 10 min. Post-PCR, the droplets from each well were analyzed using a QX200 droplet reader (Bio-Rad) and quantified based on target DNA fluorescence. The obtained data were analyzed using the QuantaSoftTM Analysis Pro software, version 1.0.596 (Bio-Rad). Additional details were reviewed recently [37].

Real-Time PCR

The EGFR T790M mutational status was evaluated using the CE-IVD validated gb ONCO EGFR (T790M) Real-Time (RT-) PCR kit (PN: 3245-048, Generi Biotech, Czech Republic). All reagents included in the kit were prepared for use according to the manufacturer's instructions. For each sample, we set two separate RT-PCR reactions. One reaction contained the Assay qPCR EGFR Control T790M and the other, the Assay qPCR EGFR MUT T790M, both in a total volume of 20 µL. 5 µL of the same gDNA sample (diluted to a final concentration of 50 ng/µL) was added to each of the two reactions. Thermal cycling conditions were as follows: initial denaturation at 95°C for 3 min, followed by 50 cycles with denaturation at 95°C for 10 s, and annealing/elongation at 60°C for 20 s. Fluorescence acquisition was set on the FAM/SYBR channel. All gDNA samples were analyzed in triplicate for the detection of EGFR T790M mutation. Each run contained two types of positive controls according to manufacturer instructions. We included one EGFR wild-type (WT) control and one EGFR T790M positive control, with 5 µL of the provided kit standards pipetted to each. Finally, to check the purity and quality of the PCR reagents, we introduced a third assay control, the so-called 'negative control'. In this case, RNase/DNase-free water was used to replace the corresponding volume of gDNA. The qRT-PCR assays were run on the Rotor-Gene Q 5plex HRM equipment (Qiagen, Germany) and the results were analyzed using the Rotor-Gene Q Series Software (version 2.3.1) (Qiagen, Germany). For each sample, the assessment of the mutational status was based on calculating fold change (FC) values from the Ct values obtained in the two separate reactions, as per the manufacturer's specifications.

Table 1: Demographic and clinicopathological data of SCC patients

Patient #	Gender	Age (years)	Area	Tobacco usage	Alcohol use	The primary site of the tumor	HPV infection	TNM	T stage	Lymph node metastases	Outcome
1	M	80	rural	no	no	lower lip	no	I	1	0	alive
2	M	67	urban	yes	no	tongue	no	IV A	3	2	dead due to disease progression
3	M	50	urban	yes	yes	tongue	no	IV A	2	3	alive
4	M	65	rural	no	yes	lower lip	no	I	1	0	alive
5	M	45	urban	yes	no	lower lip	no	III	3	1	alive
6	F	54	urban	yes	no	tongue	no	II	2	0	alive
7	M	60	rural	no	no	retromolar trigone	no	IV A	4	5	dead due to disease progression
8	M	69	urban	yes	yes	buccal mucosa	no	IV A	3	1	alive
9	F	85	rural	no	no	lower lip	no	II	2	0	alive
10	M	88	urban	no	no	cSCC of the parotid region	no	III	3	1	alive
11	M	51	rural	yes	yes	cSCC of the nasal region	no	IV A	4	2	dead due to disease progression
12	F	86	urban	no	no	cSCC of the genian region	no	I	1	0	alive

The limit of detection (LoD) declared for this assay is 5 copies per 25 µL reaction. This corresponds to a minimum detectable mutant allelic fraction of 0.05% in a background of 100,000 WT copies.

Statistical analysis

Data analysis was performed using The GraphPad Prism software (Boston, Massachusetts USA, www.graphpad.com) version 10.0.0. Patients' demographic and clinicopathological data were analyzed by descriptive statistics.

RESULTS

Patients' general characteristics

Table 1 describes the demographic and clinicopathological characteristics of the SCC patients. The clinical cohort consisted of 12 patients diagnosed with SCC of the head and neck region, encompassing 9 men (75%) and 3 women (25%). Among them, nine patients presented with OSCC (Patients #1-#9), while three subjects had cSCC (Patients #10-#12). The median age of the patients was 66 years, ranging from 45 to 88 years.

Fifty-nine percent (n=7) of the analyzed patients are from an urban environment, and 50% (n=6) of them are active smokers. Additionally, 33% (n=4) of the patients declared that they frequently consume alcohol, and 58% (n=7) presented with pathologically confirmed lymph node metastasis. Five patients were diagnosed with TNM stage IVA disease, three with stage I, and two patients each with stages II and III. All patients tested negative for the presence of high-risk HPV strains.

DNA extraction

The average concentration of DNA extracted from the archived FFPE tissues was 255.7 ng/µL (ranging from 70.2 to 484.3 ng/µL), and the average A260/A280 value was 1.83.

The A260/A280 values obtained for gDNA from FFPE tissues are within the optimal range (~1.8), indicating that the extracted gDNA is free from protein contamination. In addition, all A260/A230 values fall within the recommended range (2.0-2.2), indicating that gDNA has minimal contamination by polysaccharides. These observations confirm the obtained gDNA's suitability for subsequent molecular manipulations.

ddPCR results

The ddPCR analysis demonstrated that BRAF V600, KRAS Q61, NRAS G12/G13, and NRAS Q61 mutations were not present in the examined samples, emphasizing the rarity of these genetic alterations in the pathogenesis of squamous cell cancers. Figure 1 illustrates the absolute quantification of the NRAS Q61 mutation in FFPE samples using the ddPCR system. In addition, by exploiting the ultrahigh sensitivity of ddPCR technology, we successfully identified the presence of the EGFR Ex19Del mutation in a cSCC tumor developing in an 88-year-old male diagnosed with stage III disease (Figure 2). None of the remaining 11 SCC patients within the clinical cohort exhibited this particular mutation.

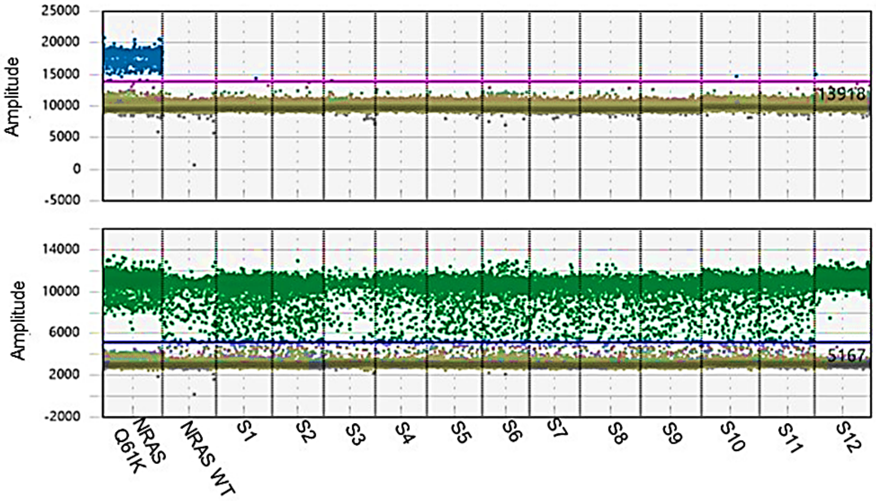

Figure 1: One-dimensional (1D) droplet fluorescence plot for NRAS Q61 mutation analysis. Blue dots represent the FAM-labeled droplets containing the NRAS Q61 -mutant allele, while green dots depict the HEX-labeled fluorescence probes associated with the NRAS WT allele. The pink line represents the threshold between positive and negative signals of the droplets. This determination enables precise NRAS Q61 mutation quantification in FFPE samples (S1-S12- SCC samples; NRAS Q61K- positive control; NRAS WT- negative control).

Real-Time PCR results

The 12 SCC samples were additionally subjected to qRT-PCR analysis to detect the EGFR T790M mutation. All SCC samples included in the study tested negative for the presence of the EGFR T790M mutation.

According to the manufacturer's recommendations, each analytical run included a positive control (containing the investigated mutation at an allelic frequency of 1%), a WT control (where only the WT allele was amplified), and a negative control (without gDNA), to investigate the purity and the quality of the reagents used. Figure 3 illustrates the positive control of the EGFR T790M RT-PCR assay, the negative control along with a sample negative for this mutation (EGFR wild-type; in blue).

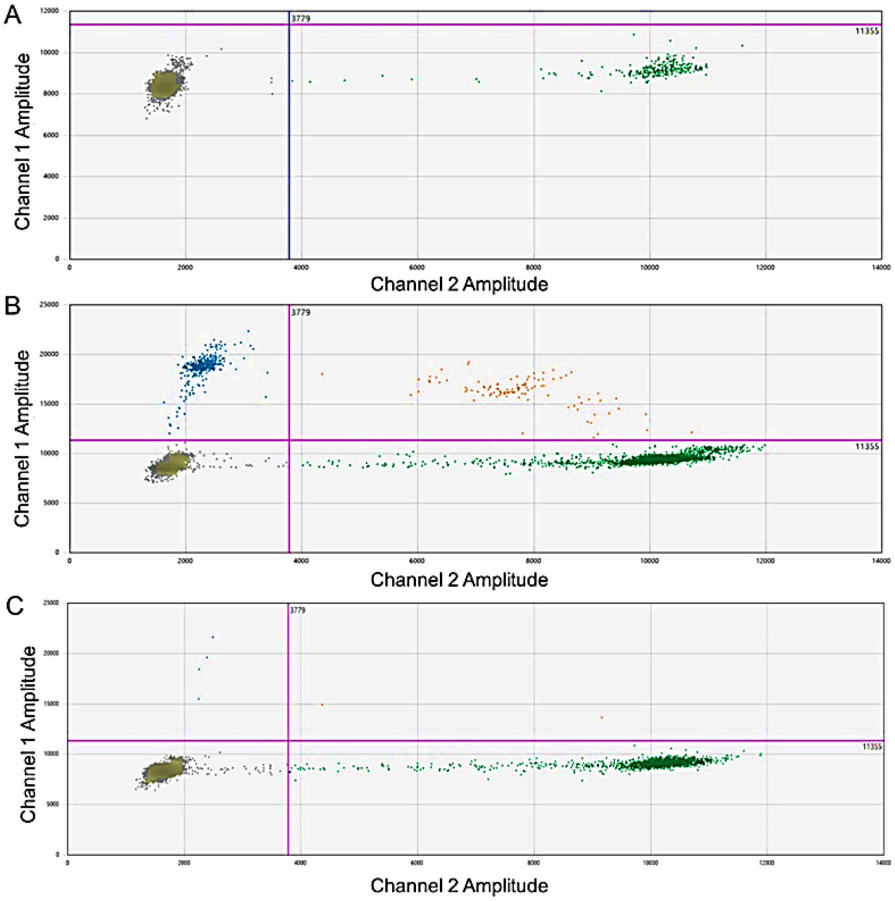

Figure 2: Two-dimensional (2D) ddPCR plots of EGFR Ex19Del mutation detection in FFPE samples. (A) ddPCR results for an EGFR wild-type DNA sample (negative control). The 2D plot illustrates that no droplets are positive for EGFR Ex19Del mutant alleles on channel 1 (FAM labeled, in blue) while EGFR Ex19 wild-type alleles are abundantly detected on channel 2 (HEX labeled, in green). Empty droplets (in grey) do not contain the EGFR Ex19Del target amplicon. (B) ddPCR results for the positive control (presenting the EGFR Ex19Del mutation). Mutant alleles are detectable on channel 1 (FAM labeled, blue). Double-positive droplets (orange) contain both mutant and wild-type EGFR Ex19 alleles. (C) ddPCR results for the cSCC tumor tested positive for EGFR Ex19Del.

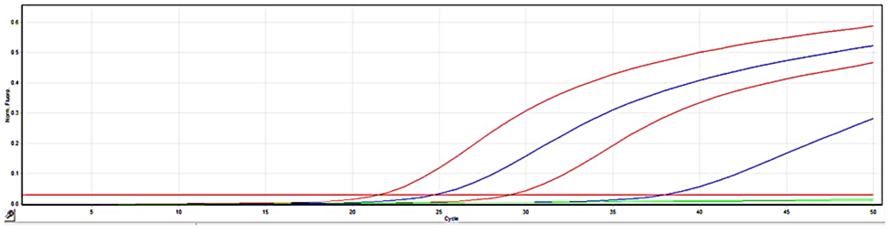

Figure 3: Determination of the EGFR T790M mutational status by RT-PCR. The positive control of the qRT-PCR analysis is marked in red, whereas the negative control is in green. The amplification curve of the EGFR WT SCC sample is depicted in blue. The threshold for the entire run was set at 0.03. A sample can be considered mutated when its FC value is lower than the cut-off FC value and the difference between the CtM of a sample and the CtC of the WT standard is lower than 13. If the latter condition is not met, or the FC value of a sample is higher than the cut-off FC, the sample is evaluated as WT.

DISCUSSION

SCC neoplasms of the head and neck are one of the most heterogeneous and aggressive tumors ever described [10]. Despite recent advances in SCC diagnosis and therapy, the prognosis of advanced patients remains poor, highlighting the need for a more comprehensive evaluation of these tumors [38–40]. From the beginning of modern medicine until now, SCCs have always been approached separately, depending on the tissue from which they originate (e.g., cutaneous SCC, oral SCC) or the anatomical region where they occur. However, in the present study, we wanted to deliver a unifying approach regarding cSCCs and HNSCCs, by analyzing the shared molecular mechanisms involved in their pathogenesis. Our point of view is also supported by the fact that the cSCC and HNSCC pathogenesis converge toward the same risk factors and genetic alterations [2,41]. Additionally, we believe this approach may facilitate a comparative examination of intrinsic tumor cell heterogeneity, stromal composition, and therapeutic efficacy across SCCs occurring in different anatomical sites, an idea that is attracting considerable research interest from the international community as well [2].

Here, we embarked on a preliminary analysis of the frequency and role of hotspot mutations in the EGFR-RAS-RAF signaling components within a clinical cohort encompassing 12 Romanian patients diagnosed with SCCs (3 cSCCs and 9 OSCC cases). We employed the third-generation PCR technology, also known as ddPCR, to screen for mutations such as BRAF V600, NRAS G12/G13, NRAS Q61K, KRAS Q61, and EGFR Ex19Del, while the mutational status of EGFR T790M was assessed using RT-PCR. None of the examined tumor specimens exhibited mutations in the BRAF, KRAS, and NRAS genes. Our findings are consistent with previous observations in the field, supporting the assertion that these genes are rarely mutated in cSCCs and HNSCCs [34,42].

The analysis of the demographic data of the subjects enrolled in the study revealed that 75% of them are men (n=9) and half (n=6) are smokers. We also observed that 58% of the subjects (n-=7) have metastases with lymph node involvement and all SCC tumors are HPV-negative (n=12).

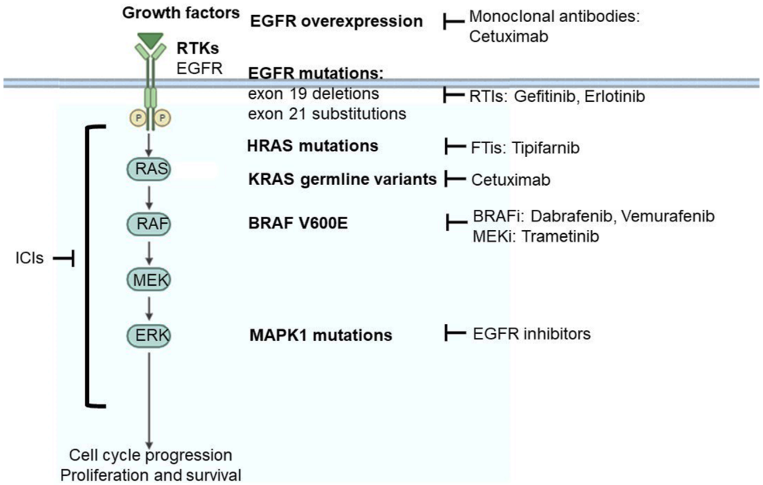

Figure 4: Precision treatment strategies for EGFR/MAPK pathway-mutated head and neck squamous cell neoplasms. ICIs- Immune checkpoint inhibitors; RTKs- Receptor tyrosine kinases; RTis- Receptor tyrosine kinase inhibitors; FTis- Farnesyl transferase inhibitors; BRAFi- BRAF inhibitors; MEKi- MEK inhibitors

However, among the 12 FFPE samples analyzed for EGFR Ex19Del, one HPV-negative cSCC tumor identified in the parotid region of a male tested positive for this mutation. Interestingly, the patient presenting with this tumor is an 88-year-old man from an urban environment who neither smokes nor drinks alcohol. Nevertheless, current literature emphasizes the role of HPV infection status as a valuable prognostic indicator for HNSCC/cSCC patients. Usually, HPV-negative SCCs display alterations in the tumor suppressors such as p53 and cell cycle regulators and present with an unfavorable prognosis compared to HPV-positive tumors, which show less genomic complexity [43]. Several research groups have examined the prevalence of EGFR Ex19Del mutations in head and neck SCCs, reporting a 1% occurrence in the Caucasian population [44] and 7.3% in the Asian population [45]. Despite providing tumor cells with different adaptive advantages via downstream hyperactivated pathways (ERK/MAPK, PI3K/Akt, and JAK/STAT), these mutations also confer sensitivity to TKIs [3]. Several ongoing clinical trials are investigating TKIs' clinical safety and efficacy in cSCC/HNSCC. Single-target TKIs gefitinib and erlotinib given as monotherapy have not demonstrated clinical efficacy in

HNSCC and cSCCs [46,47]. However, remarkable benefits have been reported when small-molecule TKIs were administered in conjunction with other therapies such as cisplatin, docetaxel, or immunotherapy [31,48]. Therefore, these mutations might be exploited for targeted pharmacological interventions in the future, once the most effective drug combinations are identified.

The evaluation of the mutational status of the MAPK signaling pathway is another hot topic in the field of SCC bio-medical research. Several recent studies potentiated that mutations in different components of the MAPK signaling pathway, such as BRAF and RAS, may serve not only as important therapeutic targets but also as valuable indicators of prognosis in SCC, indicating those patients who are most likely to respond to immunotherapy (Figure 4) [36].

This is why we focused our research on investigating these mutations in a small group of patients diagnosed with SCC of the skin and oral mucosa, the present study being also the first one of this type conducted in Romania. Recent studies have shown that even in p53-mutated HNSCC tumors, notorious for their unpredictable evolution, MAPK pathway mutations may help identify those patients with superior outcomes [36]. It is also worth mentioning that the positive prognostic value of these mutations in HNSCC has been reported independently of HPV status [36].

Bioinformatic analysis of HNSCC patient data retrieved from The Cancer Genome Atlas (TCGA) revealed that MAPK-mutant HNSCC tumors present with an increased infiltration of CD8+ T cells and dendritic cells and immune-active cytolytic and interferon-gamma signatures in situ, data that were also reported by our group [36,38,49].

Those features are not observable in HNSCC tumors with mutations in the PI3K, WNT, NOTCH, JAK/STAT, NF-kB, or TGF-beta signaling pathways [36]. Moreover, independent of tumor mutational burden (TMB), MAPK pathway mutations alone predicted those HNSCC patients who benefited the most from clinical anti-PD1/PD-L1 immunotherapy [36].

Similar prognostic roles of MAPK pathway mutations were reported in pan-cancer immunotherapy studies, suggesting that the mutational analysis of this signaling pathway might be essential to improve SCC patient risk stratification.

CONCLUSIONS

Oral and cutaneous squamous cell neoplasms (SCCs) remain a public health challenge and a topic of current scientific interest. Genetic analysis is essential to understand the biology and the clinical behavior of SCCs, unraveling potential biomarkers and therapeutic targets with practical applications in this challenging disease. Therefore, to align with the precision medicine initiatives in the field, we initiated a clinical study to explore the prevalence and significance of hotspot mutations in the EGFR-RAS-RAF signaling pathway within a small clinical cohort of Romanian patients diagnosed with squamous cell neoplasms of the head and neck. Taking into account the shortcomings reported with traditional chemotherapies, administered on a 'one size fits all' basis and resulting in poor efficacy, limited selectivity, and increased toxicity in HNSCCs/cSCCs, we are actively supporting the transition towards the adoption of more individualized anticancer agents in SCC clinical practice.

The present retrospective study emphasizes the absence of mutations in the NRAS, BRAF, and KRAS genes within a small clinical cohort of cSCC and HNSCC Romanian patients, marking the first study of this type conducted in Romania. In addition, our research underlines the remarkable sensitivity of the third-generation PCR technology, the so-called 'droplet digital PCR' (ddPCR), which may be instrumental for detecting low-frequency actionable mutations in cSCC/OSCC tissue biopsies.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research was funded by grants from the Ministry of Research, Innovation and Digitization, CCCDI-UEFISCDI, project number [PN-III-P4-PCE-2021-0549] and [PN-III-P2-2.1-PED-2021-2243], and within PNCDI III by the Core Program, implemented with the support of NASR, project [PN 23.16.01.03].

Acknowledgments

The authors would like to thank Dr. Alexandra Livescu and Dr. Ovidiu Geicu for their technical support with droplet digital PCR (ddPCR) technology.

Should Serum Levels of Creatine kinase be Evaluated in Patients with Acne Vulgaris Treated with Systemic Isotretinoin?

Abstract: *The laboratory tests that should be performed and their frequency during isotretinoin treatment are controversial. We wanted to investigate muscle and joint pain and laboratory tests in acne patients who received isotretinoin. Between April 2019 and February 2023, serum CK, AST, ALT, and GGT levels were retrospectively evaluated in acne patients before and three months after systemic isotretinoin treatment. This study included 410 patients. The median serum AST, ALT, and GGT levels significantly increased, whereas serum CK levels were similar in all patients three months after treatment. 23 (5.6%) patients revealed muscle or joint pain after treatment. No significant difference was detected in patients with or without pain in the median serum CK, AST, ALT, and GGT levels after treatment. Isotretinoin treatment at a dose of 10 mg/day was more common in patients with pain than in those without pain, whereas none of the patients who received isotretinoin 40 mg/day developed muscle or joint pain. We suggest that routine evaluation of serum CK levels is unnecessary in acne patients treated with isotretinoin. However, muscle and joint pain may develop even at doses as low as 10 mg/day. Furthermore, monitoring AST, ALT, and GGT levels may be beneficial in acne patients treated with isotretinoin.*

Keywords: *acne vulgaris; creatine kinase; isotretinoin; joint pain; muscle pain; treatment*

INTRODUCTION

Acne vulgaris is a common and chronic inflammatory skin disease that usually occurs during adolescence. Acne vulgaris may also affect adults or even initiate in adulthood. The etiopathogenesis of acne includes seborrhea, follicular hyperkeratinization, Cutibacterium acnes, and inflammation. Lesions mainly appear on the face and may lead to scarring and pigmentation changes. Therefore, acne has been associated with psychological complications such as depression and anxiety. Prompt and appropriate treatment is crucial both to improve lesions and to prevent the development of hyperpigmentation and scars [1].

Oral isotretinoin is a systemic retinoid used to treat patients with moderate to severe acne. Oral isotretinoin inhibits the function of sebaceous glands and shows anti-inflammatory effects [2]. Cheilitis is the most frequent dose-dependent side effect of isotretinoin, observed in approximately 90% of patients [3]. However, various side effects such as xerosis, pruritus, hair loss and photosensitivity have been reported after systemic isotretinoin treatment. In addition, musculoskeletal system disorders such as tendinitis and muscle and joint pain can also develop [2,3].

It has been suggested that about 50% of patients under isotretinoin treatment might develop increased serum creatine kinase (CK) levels, which indicate muscle damage [4]. Slight elevations in creatine kinase are usually reversible, while significant elevations may show rhabdomyolysis. Half of the patients with rhabdomyolysis are asymptomatic, and a minority of patients may develop fatigue and myalgia. Therefore, it has been proposed that it might be useful to evaluate serum CK levels before the initiation of isotretinoin treatment and regularly or when necessary during treatment [5].

In addition, patients with acne are usually monitored monthly, performing laboratory tests for potential side effects such as deterioration of the lipid profile and liver enzymes or complete blood count abnormalities such as leukopenia [6]. However, no consensus exists on the tests that should be performed in patients treated with isotretinoin. For instance, routine evaluation of complete blood count has not been recommended by Hansen et al. [6,7]. Moreover, it is controversial whether frequent laboratory testing is necessary during systemic isotretinoin treatment. It has been reported that laboratory tests might be checked before and two months after treatment, and in case the results are within normal limits, there is no need for further evaluation [6,8].

Herein, we investigated muscle and joint pain and serum levels of CK, aspartate aminotransferase (AST), alanine aminotransferase (ALT), and gamma-glutamyl transferase (GGT) in patients with acne vulgaris treated with systemic isotretinoin.

MATERIALS AND METHODS

Gazi University Ethics Committee approval was obtained before this study (approval number: 2023-210). Between April 2019 and February 2023, medical records of patients with acne vulgaris treated with systemic isotretinoin were reviewed retrospectively. Age, sex, past medical history, chronic medication use, duration of acne, the age of onset of acne, and the severity of acne were evaluated. The severity of acne was classified as papulopustular and nodular acne. Isotretinoin dose, muscle or joint pain developed after isotretinoin treatment, localization of the pain, and time to onset of pain after treatment were also noted. In addition, serum levels of CK, AST, ALT, and GGT before and three months after the initiation of systemic isotretinoin treatment were evaluated by the biochemistry panel. The reference range was (46-171 U/L) for CK, (<34 U/L) for AST, (<49 U/L) for ALT and (<73 U/L) for GGT. Exclusion criteria were having liver and kidney diseases, using medications that may affect liver or muscle enzymes and intense exercise.

Statistical analysis was performed using SPSS version 25.0. Quantitative variables were stated as mean ± standard deviation or median (interquartile range). Categorical variables were stated as counts and percentages. The normality of the distribution of the data was evaluated by Kolmogorov-Smirnov test. Wilcoxon signed ranks test, chi-square test, and Mann-Whitney U test were used to determine the differences between the groups. P value less than 0.05 was considered statistically significant.

RESULTS

This study included 410 patients, 324 (79%) females and 86 (21%) males. The median age of the patients was 21 (6) years (range: 14-34 years). The past medical history was unremarkable in 391 (95.4%) patients. The characteristics of the patients are stated in Table 1. None of the patients reported regular use of a medication or excessive alcohol consumption. The patients were treated with oral isotretinoin at a dose of 10 to 40 mg daily. Among females, 220 (67.9%) had papulopustular, 104 (32.1%) had nodular acne, whereas among males, 44 (51.2%) had papulopustular and 42 (48.8%) had nodular acne (p=0.005). The median acne duration was 5 (5) years, (range: 1-20 years) in patients with papulopustular acne and 5 (4) years, (range: 1-20 years) in nodular acne (p=0.174). The median age of onset of disease was 15 (4) years, in patients with both papulopustular and nodular acne (p=0.693).

Table 1: Characteristics of patients with acne vulgaris

	Patients with acne vulgaris (n = 410)
Sex, n (%)	Females: 324 (79) Males: 86 (21)
Age Median (IQR), years Range, years	 21 (6) 14-34
Medical history, n (%)	Unremarkable, 391 (95.4) Seborrheic dermatitis, 3 (0.7) Asthma, 3 (0.7) Depression, 2 (0.5) Hashimoto's thyroiditis, 2 (0.5) Insulin resistance, 2 (0.5) Thalassaemia carrier, 2 (0.5) Allergic rhinitis, 1 (0.2) Urticaria, 1 (0.2) Familial Mediterranean fever, 1 (0.2) ITP, 1 (0.2) Mitral valve insufficiency, 1 (0.2)
Acne duration Median (IQR), years Range, years	 5 (5) 1-20
Age of onset of acne Median (IQR), years Range, years	 15 (4) 10-22
Severity of acne, n (%)	Papulopustular, 264 (64.4) Nodular, 146 (35.6)

IQR: Interquartile range. ITP: Idiopathic thrombocytopenic purpura. This study included 324 females and 86 males with acne between the ages of 14 and 34 years

The median serum levels of AST (p<0.001), ALT (p=0.024), and GGT (p<0.001) statistically significantly increased in all patients three months after systemic isotretinoin treatment. However, no statistically significant difference was ob-served in serum CK levels in all patients three months after systemic isotretinoin treatment (p=0.991) (Table 2). On the other hand, high serum GGT levels were significantly more frequent after isotretinoin treatment than those before treatment (p=0.012) (Table 3).

23 (5.6%) patients revealed muscle or joint pain during systemic isotretinoin treatment, while 387 (94.4%) patients did not have any musculoskeletal complaints. Low back pain was the most common and detected in 16 (3.9%) patients. In

addition, widespread pain was observed in 5 (1.2%) patients and leg pain in 2 (0.5%) patients (Table 4).

Table 2: Laboratory test results of patients with acne vulgaris before and three months after isotretinoin treatment

	Before treatment	After treatment	P value
CK, median (IQR) U/L Range: U/L	74 (43) 30-756	75 (40) 32-717	0.991
AST, median (IQR) U/L Range: U/L	18 (5) 9-215	21 (6) 8-853	<0.001
ALT, median (IQR) U/L Range: U/L	13 (9) 3-95	14 (9) 4-250	0.024
GGT, median (IQR) U/L Range: U/L	13 (6) 5-60	16 (7) 6-110	<0.001

ALT: Alanine aminotransferase. AST: Aspartate aminotransferase. CK: Creatine kinase. GGT: Gamma-glutamyl transferase. IQR: Interquartile range. A statistically significant increase was observed in serum levels of AST, ALT, and GGT, whereas no significant difference was observed in serum CK levels three months after systemic isotretinoin treatment.

Table 3: The frequency of high enzyme levels in patients with acne vulgaris before and three months after isotretinoin treatment

	Before treatment n (%)	After treatment n (%)	P value
CK	Normal: 379 (92.4) High: 31 (7.6)	Normal: 377 (92) High: 33 (8)	0.739
AST	Normal: 403 (98.3) High: 7 (1.7)	Normal: 398 (97.1) High: 12 (2.9)	0.251
ALT	Normal: 398 (97.1) High: 12 (2.9)	Normal: 395 (96.3) High: 15 (3.7)	0.532
GGT	Normal: 404 (98.5) High: 6 (1.5)	Normal: 393 (95.9) High: 17 (4.1)	0.012

ALT: Alanine aminotransferase. AST: Aspartate aminotransferase. CK: Creatine kinase. GGT: Gamma-glutamyl transferase. High serum GGT levels were significantly more frequent after isotretinoin treatment

Table 4: Patients with acne vulgaris who revealed muscle or joint pain after systemic isotretinoin treatment

	Patients n (%)
Muscle or joint pain	Yes: 23 (5.6) No: 387 (94.4)
Localization of the pain	Low back: 16 (3.9) Widespread: 5 (1.2) Leg: 2 (0.5)
Time to onset of pain after treatment	Within the first month: 5 (1.2) Within the second month: 9 (2.2) Within the third month: 9 (2.2)
Isotretinoin dose	10 mg/day: 6 (26.1) 20 mg/day: 10 (43.5) 30 mg/day: 7 (30.4)

Muscle or joint pain was detected in 23 (5.6%) patients with acne vulgaris after systemic isotretinoin treatment. Among them, low back pain was the most common

When patients were evaluated according to whether muscle and joint pain developed or not, no difference was observed in age (p=0.640), gender (p=0.436), duration of acne (p=0.919), the age of onset of acne (p=0.898) and the severity of acne (p=0.660). Nevertheless, among patients who developed muscle or joint pain, 6 (26.1%) received oral isotretinoin 10 mg/day, 10 (43.5%) received 20 mg/day, and 7 (30.4%) received 30 mg/day, whereas, among patients without pain, 13 (3.4%) received oral isotretinoin 10 mg/day, 177 (45.7%) received 20 mg/day, 174 (45%) received 30 mg/day and 23 (5.9%) received 40 mg/day (p=0.001). Furthermore, no statistically significant difference was detected in patients with or without pain in the median serum levels of CK, AST, ALT and GGT before and after systemic isotretinoin treatment (Table 5).

DISCUSSION

Musculoskeletal symptoms have been reported in about 25% to 87% of patients under isotretinoin treatment [9,10]. Various adverse effects have been described in patients with acne following systemic isotretinoin treatment such as myalgia, arthralgia, gout, spondyloarthritis, low back pain, muscle weakness, muscle stiffness, and myopathy [9,11,12]. Among them, temporary arthralgia or myalgia is the most common [13]. Musculoskeletal symptoms have been described even with low-dose regimens [9]. Drozd et al. revealed that low back pain was the most frequent musculoskeletal complaint in patients with skin diseases who received isotretinoin and that symptoms initiated within the first month of the treatment in 32.9% of patients, whereas between the second and the sixth month in 64.7% of patients. A dose reduction or temporary discontinuation of isotretinoin was recommended in patients with muscle pain or high CK levels [10].

On the contrary, De Francesco et al. stated that arthritis did not have a dose-dependent effect that it was unnecessary to discontinue the drug or reduce the dose, and that isotretinoin treatment could be continued at the same amount without complications [13]. Furthermore, Feily reported patients with acne aged 18 to 29 years who developed musculoskeletal symptoms such as back and leg pain within two months after the initiation of oral isotretinoin treatment and responded to folic acid and vitamin B12 supply [14].

Table 5: Characteristics and laboratory test results of patients with and without muscle or joint pain after systemic isotretinoin treatment

	Patients with pain	Patients without pain	P value
Sex, n (%)	Female: 20 (87) Male: 3 (13)	Female: 304 (78.6) Male: 83 (21.4)	0.436
Age, median (IQR) years Range, years	21 (4) 16-31	21 (6) 14-34	0.640
Acne duration, median (IQR) years Range, years	5 (2) 1-14	5 (5) 1-20	0.919
Age of onset of acne, median (IQR) years Range, years	15 (3) 10-22	15 (4) 10-22	0.898
Acne severity, n (%)	Papulopustular: 16 (69.6) Nodular: 7 (30.4)	Papulopustular: 248 (64.1) Nodular: 139 (35.9)	0.660
Patients received different isotretinoin doses, n (%)	10 mg/day: 6 (26.1) 20 mg/day: 10 (43.5) 30 mg/day: 7 (30.4)	10 mg/day: 13 (3.4) 20 mg/day: 177 (45.7) 30 mg/day: 174 (45) 40 mg/day: 23 (5.9)	0.001
Before treatment CK, median (IQR) U/L n (%)	70 (29) Normal: 22 (95.7) High: 1 (4.3)	75 (45) Normal: 357 (92.2) High: 30 (7.8)	0.494 0.549

AST, median (IQR) U/L n (%)	21 (8) Normal: 23 (100) High: 0	21 (5) Normal: 375 (96.9) High: 12 (3.1)	0.649 0.392
ALT, median (IQR) U/L n (%)	15 (14) Normal: 21 (91.3) High: 2 (8.7)	14 (9) Normal: 374 (96.6) High: 13 (3.4)	0.832 0.203
GGT, median (IQR) U/L n (%)	16 (9) Normal: 23 (100) High: 0	16 (7) Normal: 370 (95.6) High: 17 (4.4)	0.285 0.613

Muscle damage due to isotretinoin treatment is generally mild and presents with well-tolerated pain or tenderness of muscles and increased serum CK levels [15,16]. However, isotretinoin can lead to severe muscle damage such as rhabdomyolysis which may result in renal insufficiency and even mortality [5,16]. Evaluation of CK has been recommended in patients treated with oral isotretinoin, especially in those who exercise regularly [5,15]. Furthermore, during follow-up, muscle and joint pain should be questioned [16]. Besides CK, laboratory tests performed to evaluate possible side effects in patients treated with systemic isotretinoin include serum levels of AST, ALT, lipid panel, and complete blood count [17]. The American Academy of Dermatology guidelines of care for the management of acne vulgaris recommend monitoring liver function tests and serum lipids until treatment response is achieved [18]. Zane et al. stated that among patients who used isotretinoin, 11% developed increased serum levels of AST or ALT which was usually mild and reversible, and that they principally evaluated ALT levels since ALT was more specifically indicated liver damage than AST [19]. On the other hand, Webster et al. stated that although AST and ALT were used to detect liver damage, they were not specific to the liver, they were also found in muscles, whereas GGT was a liver-specific and CK was a muscle-specific enzyme. In addition, Webster et al. suggested that monitoring serum GGT level was more beneficial than AST and ALT to detect liver damage in patients treated with isotretinoin for acne and that the increase in AST originated from the muscle rather than the liver [17].

Within this study, the median serum levels of CK, AST, ALT, and GGT were increased three months after oral isotretinoin treatment, however, a statistically significant increase was detected in serum AST (p<0.001), ALT (p=0.024) and GGT (p<0.001) levels. The number of patients with high serum CK, AST, ALT, and GGT levels increased after treatment. Nevertheless, a statistically significant increase was observed only in the number of patients with high GGT levels (p=0.012).

Muscle or joint pain occurred in 23 (5.6%) patients, among them, low back pain was the most common. There was no significant difference in age, gender, acne severity, acne duration, age of onset of acne, and serum CK, AST, ALT, and GGT levels between patients who developed and did not develop pain after isotretinoin treatment. On the other hand, isotretinoin treatment dose differed significantly in patients with and without pain (p=0.001). Treatment with isotretinoin at a dose of 10 mg/day was more common in patients with muscle or joint pain than in those without pain, whereas none of the patients who received isotretinoin 40 mg/day developed muscle or joint pain.

CONCLUSIONS

In conclusion, since no significant change was detected in serum CK levels with isotretinoin treatment, as well as no association was observed between serum CK levels and muscle or joint pain, we suggest that routine evaluation of serum CK levels is not necessary in patients with acne vulgar-is treated with isotretinoin. Although muscle or joint pain was observed in 5.6% of patients with acne vulgaris used isotretinoin, it should be kept in mind that muscle and joint pain may develop regardless of the isotretinoin dose, even at doses as low as 10 mg daily. Our results revealed a significant increase in serum AST, ALT, and GGT levels due to isotretinoin which indicated that monitoring serum AST, ALT, and GGT levels might be beneficial in patients with acne vulgaris treated with systemic isotretinoin.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research received no external funding.

Abstract: *Resilience refers to the means and ability to deal with adverse conditions. Resilience is defined as the ability of the system to recover easily after disturbances and changes in the system and the ability of the organization to respond quickly to them. The resilient system can withstand environmental pressures so that it can provide optimal performance in critical situations. Resilience in the use of healthcare services is related to reducing vulnerability to shocks caused by natural disasters and increasing adaptive capacity due to improved measures and opportunities. Considering the importance of evaluation, monitoring, and planning to improve user resilience against accidents, spatial evaluation and redefinition of the use of health and medical services to prepare a comprehensive model for measuring the resilience of hospitals against accidents and calamities Naturally, at the top of which is the coronavirus epidemic, it is necessary. The aim of the current study is a comprehensive review of the factors influencing the redefinition of the spatial pattern of therapeutic uses in big cities at the time of the emergence of a pandemic disease with a resilience approach. It is expected that the managers and decision-makers of the country's health field can use the results of the present research for better planning.*

Keywords: *Resilience, Economic factors, Metropolis, Healthcare services, Coronavirus*

INTRODUCTION

The accelerated and unbalanced development of physical space in some countries in the last few decades has brought adverse social, economic, and physical effects and consequences [1].

The exorbitant costs of urban transportation and services, energy waste, wasting material and social capital in the city, intensifying social segregation, environmental destruction, lack of beauty and cohesion of the city environment, social identitylessness, and instability are among the most important problems of cities in the discussion [2]. Undesirable development of physical space and low density of cities are considered. We are now living in the era of urbanization and urban development, where the ecology and morphology of cities have been increasingly affected by human and natural activities, with the development of urbanization and the desire of people to live in cities, as well as the occurrence of such diseases [3]. In recent years, the existing healthcare spaces in big cities have been seriously challenged. So during the peak of the epidemic, it reaches its peak time and the lack of these uses (hospitals and other medical centers) is felt in urban communities. For this reason, in recent years, many cities have implemented measures to create such spaces (sanitary-therapeutic) during the crisis of pandemic diseases [4].

In Iran, especially since the 1950s, the need to compile different levels of the health network cycle of the country has been felt and based on specific studies of culture, geographical environment, the population of each region, and various types of treatment facilities, from health centers to hospitals. This important thing has been specified and defined. Of course, the country's goal of these divisions is to create the possibility of greater efficiency of financial, equipment, construction, human resources, etc. [5]. In the shortest possible time and with the highest quality of treatment and health, especially when pandemic diseases (coronavirus) occur. But the format of city managers looks for other things beyond these necessities [6]. Improving access to medical services as an indicator of quality of life and social welfare plays an important role. Equal access to medical services for different sections of society in a fair and balanced distribution of these services is one of the important foundations of social welfare [7]. Treatment spaces can be designed in 2 formats: 1) Health spaces and 2) Health-treatment spaces The basis of work in the health management system of countries is the discussion of the care and survival system of health centers and the chain of health spaces. Along with and parallel to the completion of this chain, the treatment system is proposed and then the treatment spaces are defined [8]. Although in most countries, the health care system is necessarily more complete than the treatment chain, but the possibility of full adaptation of these two chains to provide health services in cities is one of the ideals of every country. Today, the growth and development of urbanization have led to the creation of many facilities, but it should be kept in mind that with the growth of urbanization, the factors that because crises have also increased [9]. The issue of access to urban services is one of the important issues that affect the city from various dimensions. In some cases, the lack of proper access to some uses puts people's health at risk. And suitable for it is necessary for all members of the society to access services from two dimensions: the access of the target space is not the space that can be examined [10]. Access is one of the key components affecting the important quality of the urban environment, among the important ideals in this field is homogeneous access with the highest degree related to urban facilities [11]. The sustainability of cities and even megacities when pandemic diseases start, depends on the function and ability and more optimal use of health and treatment spaces, especially urban hospitals, therefore, based on the announced policies of the urban planning and treatment system of each country, it is effective for the life of that city [12]. It will be useful, however, when such crises (pandemic disease) occur, in such a way that it shows the best reaction and response in the shortest possible time during the accident. This will require the review, definition, and re-review of the uses of health and treatment spaces during pandemic crises (after the start of the coronavirus) [13]. Natural and man-made disasters inflict various types of damages, injuries, and death on the affected communities. Such disasters can disrupt various infrastructures and facilities, including hospitals, schools, transportation systems, and emergency services [14]. Non-attendance or lack of preparation in the continuity of services in emergencies caused by accidents has destructive and unfavorable effects on the responsiveness of hospitals. Recent disasters around the world have resulted in irreparable damage to hospitals and disruption of medical services [15]. One of the calamities that has spread all over the world today and has affected all the countries of the world is the coronavirus. In December 2019, the first case of coronavirus was reported in Wuhan, China, and due to the high death rate caused by it, it caused global panic. The rapid transmission of this virus has led to the diagnosis of more than a few million patients over the past two years [16]. A significant increase in the number of infected patients has made the work of medical and health centers difficult in dealing with this disease. Disruption and inconsistency in the provision of medical and health services can lead to irreparable losses and damages [17]. Therefore, it is very important to encourage researchers and decision-makers in order to prepare strategies for improving resilience in health and treatment centers [18]. The aim of the current study is a comprehensive review of the factors influencing the redefinition of the spatial pattern of therapeutic uses in big cities at the time of the emergence of a pandemic disease with a resilience approach.

METHODS

This research is a scoping review that has been conducted by searching for systematic studies to identify the factors influencing the redefining of the spatial pattern of therapeutic uses in big cities at the time of the emergence of a new and re-emerging pandemic disease with a resilience approach using the Cochrane protocol in 1402. accepted. The study inclusion criteria were defined as follows:

Publication date: Due to the comprehensiveness and breadth of both keywords of the research, preparedness against emerging and re-emerging pandemic diseases and the spatial pattern of therapeutic uses of megacities were searched with a resilience approach. In terms of time, only researches that were published in the last decade, from 2010 to 2023 AD and from 1390 to 1402 AD, were examined.

Language: Due to time, financial, and manpower limitations, only the research published in English or Farsi was examined. On the other hand, to evaluate the quality of the studies and use them in the review, only the researchers whose texts are accessible to the researcher have been used.

Place of publication: Relevant sources published in reputable scientific journals, conferences, and theses were used.

Type of studies: Quantitative, qualitative, mixed, or review studies were examined.

The extracted sources were examined by two researchers independently. In this way, the mentioned keywords were first searched in reliable Persian and English scientific databases, including Direct Science, Scopus, PubMed, Google Scholar, and SID in the period from 2010 to 2023. The reason for choosing these databases was their validity and comprehensiveness including a large number of authoritative English-language publications in the field of health and environmental studies, as well as the availability of access to most of the articles and books of these databases for the researcher. In the next step, articles whose full text could not be accessed were excluded from the study. Then, the articles that appeared more than once in the search results were removed using Endnote software, and according to the title of the article, articles not related to the topic were also removed. In the next step, the abstracts of these articles were studied more deeply, and according to the proposed limitations, at this stage, the articles that did not meet the mentioned criteria were removed. Finally, to evaluate the quality of the articles, the standard evaluation checklist (Critical Appraisal Skills Program: CASP) of qualitative studies was used, and the studies that received a score of 25 or higher were included in the study. Due to the inconsistency of included studies and the impossibility of meta-analysis, the meta-synthesis method was used to analyze the data. Out of 2583 reviewed articles, after considering the entry and exit criteria, 37 articles were included in the final review.

RESULTS AND DISCUSSION

The topic of social justice was first introduced to the science of geography by David Harvey in the book Social Justice and the City in 1976. In this book, Harvey has examined social justice with a radical Marxist perspective. In general, many articles and theses have been presented in the discussion of social justice in Iran, the most important of which are mentioned in the following. English et al. (2021) in the research they conducted in the city of Seoul, South Korea, have concluded that in a city, despite having enough services per capita (such as a park), due to improper distribution, they may be available to everyone.

Therefore, the residents have evaluated the distribution of parks concerning the population and other uses of the city and the proposed density of the areas. The results of their findings show that some of the residential areas in Seoul are deprived of access to city parks [19]. Esser et al. (2019) conducted research titled Capacity in Education: A Step Towards Social Justice, which was carried out from a 3-year collaborative activity of 8 primary schools in Darussalam and the coastal region of Powani in Tanzania, and concluded that there are countless obstacles to capacity (Education) In the world, communities and school levels exist, and in Tanzania some progress has been made in terms of (education) capacity, but equity and quality of education still have a long way to go [20].

In their article, Yasobant et al. (2019) express the idea of locating hospital centers in cities, in general, there is no long history in the field of locating medical and health service centers, and it goes back to the 1970s, since 1979, the department Social security health in England paid attention to the strategic development of medical and health service centers in cities, and it was followed in Austria in 1980 and 1982 [21].

Manenti et al. (2020) in an article on urban health addressed the evidence, challenges and guidelines. As a result, we note that although in this review we highlight challenges, this is due to the potential power of urban health research and the importance of studying health. Although the study of urban health encompasses considerable complexity, research with specific research questions and appropriate study designs can improve our understanding of the relationship between specific characteristics of urban nature and health in both specific cities and as generalizable to National cities and recent methodological advances, especially the widespread adoption of multilevel methods in public health research, have made it possible to test hypotheses about urban characteristics and their association with specific health outcomes. Finally, newer methods may contribute to a better understanding of competing influences on the health of urban populations over time. Such research can inform local interventions and policies in urban areas. We hope that efforts such as this review aim to build Our thinking about cities and health will help stimulate both empirical and theoretical developments that can lead to improved health in cities around the world [22].

Schäfer et al. (2021) in research have examined the spatial access of primary care, including methods, challenges, and concepts, and finally concluded that almost all healthcare centers to date, whether based on simple or complex measures, are limited to social inequality in access to health services and to investigate how much primary care centers affect people's health [23]. Sevá et al. (2017) have conducted a research regarding the access and use of health services in Ghana, in which the aim is to investigating the impact of access and socioeconomic factors on the use of health services in developing countries (specifically Ghana). Utilization of health services in Ghana distribution shows a significant difference between rural and urban areas in all variables, except health status and age. Even though the metropolis uses relatively more health services than the villages, the difference in the health status (need) of the two districts is not significant. The coefficient between the two districts is insignificant. Therefore, there is a difference between the need and use between the districts. Success is part of a local understanding of the dimensions and determinants of access to health services, as well as concrete efforts to improve services for the poor. Part of the innovations in health care financing and regulation of care promises to improve access for the poor in any case.

The challenge remains to find ways to ensure that vulnerable populations have a say in how strategies are developed, implemented, and formulated, and to ensure that information and incentives are channeled in ways that can lead to improvements in access for the poor. It is expressed whether or not it can be given [24].

Morris et al. (2021) researched regarding the regulation of access and use of health services. The results showed, first, descriptively, how the countries are using different doctors to refer to a specialist. Second, a multilevel analysis shows how regulatory indicators affect each quantity of care consumed in a country, and finally, they examine how institutional structure affects differences in service utilization among groups with different incomes, education levels, and Health statuses [25].

Lingam et al. (2021) studied the determinants and pattern of health service consumption among graduate students and the result of this research showed that the healthcare system in Pakistan includes public and private health centers. In Pakistan, the majority of doctors are in the regions. They live in the city and attract the educated classes than the private sector. The use of public healthcare facilities is not the main priority of the educated class of the country, and government officials should pay more attention to making it more common for the people [26].

Gatto et al. (2022) studied poverty and access to health care in developing countries. The result of this research showed that despite the progress in access to health care in developing countries, a significant number of their population has limited access. Poor countries have a higher burden of disease but usually have less access to health care. Whether based on geographical access, accessibility, physiological access, acceptance or quality of care. However, recent studies show that this exodus is inevitable [27].

Peng (2020) discussed the optimal location for the construction of a hospital. In this study, the AHP method was used as one of the methods of multi-criteria analysis and GIS. The result of the study showed the use of the hierarchical analysis process in location. The hospital has been very efficient in the study area [28].

Lewis et al. (2021) investigated the improvement of access to health services in urban and regional areas for indigenous people. The results of this literature study provide information about barriers to access to health and mental health services for local people living in urban and regional communities. These barriers can be classified as barriers of accessibility (physical accessibility), affordability, appropriateness, and cultural acceptance [29].

Sousa et al. (2021) analyzed the equity and use of health services in Uganda in a research that focused on several factors (supply and demand) that affect the access and use of health services in Uganda, such as Education, age, household expenses, use of the outpatient department, hospital capacity and the distance from medical services, this study has analyzed a number of measures that are used in the implementation of policies, especially in the main fields. Key policies such as malaria, tuberculosis, and HIV/AIDS have been created. The analysis shows, however, that despite efforts to improve health by improving health outcomes for people, mountainous challenges still remain. For example, living near essential health services, although they work as an incentive to use care, does not necessarily ensure that health services are actually used. Secondly, the elimination of the usage fees of all government centers will increase the utilization of new healthcare facilities, especially fixed and fee-based service providers with catastrophic costs [30].

Joshi et al. (2022) in a study investigated the access and use of health care among rural households in Nigeria. The results showed that the average age of the respondents was 46 years and the average household was 8 people. The majority of the respondents, 43.5%, do not have formal education and the main occupations are agricultural officials. 58% of the respondents have access to medical services, while only 42.5% use these services. Most of the respondents, 40.5%, are 5-9 kilometers away from accessing medical centers. Accessibility indicators show unequal access to modern health facilities in the study area, so this study recommends that rural development policies should create an organizational environment to increase participation and access to justice in the provision of modern health care throughout rural areas. strengthen in the country [31].

McKenzie 2017, in an article on the access and use of health services in Massachusetts, the United States, conducted a qualitative study of the views and experiences of immigrant women in Brazil. The findings of the research show that illegal immigrant women in Brazil are more likely to access health services in countries that have health services. They are satisfied with the global level. Health care is critical to quality of life, but many immigrants and ethnic minorities often lack adequate access to health care, increasing health risks. This study adds to the current literature on healthcare access and use by immigrants living in the United States and also provides new information on Brazilian immigrant women's perspectives and experiences of healthcare access and use in Massachusetts, USA to give While identifying the opportunities to improve the services and health of the entire immigrant population [32].

Allam et al. (2022) examined the relationship between transportation networks and healthcare services and their impact on urban sprawl. The findings of this study show that there are more dynamic relationships between the content of these urban components and access to health care [33].

Das et al. (2021) investigated the design of decision support systems for access to space services. The results of the research showed that improving access to health care can help reduce health costs, increase healthcare equity, and improve health outcomes. Through our research, we have designed a new application-based framework for measuring access to health care and a practical example of SDSS that is rooted in the theoretical concepts of BM and existing FCA methods. Our unique method to obtain the weight of the population characteristics is provided by the use of predictive analysis using real data to evaluate the need to integrate non-spatial factors into existing algorithms in the creation of SPAI. The findings should encourage future research to further examine how demographic characteristics may shape the demand for health care gives the hardness by considering the actual manufacturer's needs [34].

Cotta et al., 2020, reviewed the approaches to measuring potential spatial access to urban health services in a research where they examined the types of distances and their related issues [35].

Berendes et al. (2018) examined the urban status and health competence of critical issues and exercises, and it was concluded that if the global community is serious about the sustainable development goals of SDGs, more attention should be paid to understanding and taking action to improve urban conditions to have a life and social and economic conditions that can promote health competence. The result of the research showed that healthy and fair urban places are very important to achieve health for all the population, however, strict emphasis is placed on built environments or risk factors. A single person does not address the numerous and often cumulative social and environmental obstacles that exist in cities today and does not help the inequalities that burden poor urban communities. To collaborate or help the urban poor to analyze and solve problems. We realize that this will not be easy and the evidence base for how to do this effectively is still emerging. Our challenge is great, but in an urban planet public health Environment is urban health and health justice should be our goal [36].

Pak et al. (2018) investigated network and spatial analysis to evaluate and guide decision-making about equal access and health services in the general patient care system in Ederdamora (Spain). The simultaneous use of access and coverage maps to show the relative distribution of resources in a population, while showing the coverage levels according to the time of access to physical and professional facilities with and without administrative restrictions, can help decision-makers to improve the optimal level of stocks in a region. Large and low-density geography is very valuable [37].

Coccia et al. 2020 studied the issue of access to health care by urban refugees and the host population around Uganda. The results of this research showed that health services were available every five kilometers for both refugees and the host population. Refugees are generally unable to pay for access to health services, including transportation, research, essential drugs, and other informal costs. Refugees' perception of public health services is weaker compared to general citizens. Primarily due to long-term expectations of a small number of inadequate essential drug services, perceived discrimination and the existence of unofficial fees [38].

Paris et al. (2020) in a study to measure the resilience of traditional societies against natural disasters have concluded that traditional societies face natural disasters using four dimensions: nature of risk, level of resilience, cultural structure and policies. Managers can show resilience in the face of disasters [39].

Finn (2022) conducted a research as a place-based model to understand the resilience of local communities against natural disasters. This study presents a new framework of the place of urban resilience in order to improve the method of assessing resilience against disasters at the local and regional level, and a set of variables have been considered in this study as the first step in the target research. The final output of this research is presented in the form of environmental, social, economic, institutional, infrastructure, and competence of society [40].

Park et al (2022) in an article titled "Towards resilient regions: regional development policy" use a descriptive-analytical method and emphasizes the economic dimension of resilience and analyzing indicators of employment rates, large-scale economic centers, income and production gross and knowledge mobility introduced the process of making the regions resilient [41].

Plastina et al (2019) worked on an article entitled Regional planning and the future of resilience in the Ning ladder coral coastal region of Australia in 2019, which was the indicator of resilience and the amount of tourist attraction, which finally reached the correlation between resilience and tourist attraction [42].

Teng et al (2022) in an article titled "Tissue-based identification of old urban neighborhoods in Hyderabad, India using remote sensing data with a renovation approach, concluded that the location map of worn-out tissue is an efficient tool in identifying areas." The densely populated city can be used as a reliable source for vulnerability and resilience assessment in the next step. The presented method allows for quick analysis and comparison of multi-temporal data and can be used in many densely developing cities around the world [43].

Acharya et al. (2017) collected the articles and opinions of different people in one collection and investigated the reconstruction of built environments after disasters in order to increase resilience and found that resilience should be considered among the necessities of reconstruction [44].

Hasson et al. (2022) categorized urban resilience indicators from a landscape ecologist perspective and the result of this article introduces five urban design and planning indicators to create urban resilience, which include redundancy, multi-functional (biodiversity) Being an urban system, urban ecological networks and connection with connections, adaptive design or adapting to changes, he still emphasizes the combination of ecological principles and urban planning to achieve urban resilience [45].

Ferdowsi and Arkhodi (2016) in an article entitled "Evaluation of health and medical resilience of Semnan province cities against natural disasters" stated that due to the high importance of health and medical resources in order to improve the resilience of settlements against natural disasters Naturally, managers and planners should have a special approach to providing healthcare facilities and infrastructure. The purpose of this research is to evaluate the cities of Semnan province based on health-medical indicators effective in resilience. In this research, the desired indicators have been evaluated using the Vikor model. According to the results, the cities of Shahrood, Damghan, Garmsar, Aradan and Sorkheh have a more efficient performance in providing services during the occurrence of natural disasters by having proper medical facilities and infrastructures, and in other words, they have favorable health-medical resilience in the face of natural disasters. They will have accidents. On the other hand, the cities of Mahdishahr, Miami and Semnan, due to the lack of appropriate proportion between the population and medical facilities and infrastructure, will have low resilience when faced with accidents compared to other parts of the province. In general, by evaluating and analyzing this process in Semnan province and resilience strategies, managers and planners can lead the cities of the province to strengthen resilience against natural hazards, considering the existing capacities and competitive advantages [46].

Saffari Darberazi et al. (2019) in an article entitled "Designing a Comprehensive Hospital Resilience Model in the Face of Corona Disease" stated that healthcare centers should be able to quickly adapt to catastrophic events such as natural and human disasters. One of the ways to deal with various disasters in healthcare centers is to increase resilience.

The current research aimed to design a comprehensive hospital resilience model by identifying the factors affecting hospital resilience, and the way these factors are related in the face of the corona disease. At first, by using the background study of the research, the effective factors on hospital resilience were identified, and then by using the interpretive structural modeling technique, the communication model between the identified factors was obtained. The conceptual model obtained from interpretive structural modeling was fitted using Smart PLS software version three. For this purpose, the questionnaire containing 33 questions was provided to 80 managers, experts, and employees of Yazd teaching hospitals. The research results indicate the identification of eight general factors affecting hospital resilience. The eight factors identified in the present study were structured in four general levels by interpretive structural modeling. The starting level of the model is the factors of "sustainability" and "information technology and communication system". Also, the model-fitting results confirm the relationships formed by interpretive structural modeling. Based on the results of the present research, the country's health and treatment managers can use to make the country's hospitals resilient in the face of natural disasters and unforeseen events [47].

Ebrahimzadeh et al (2009) in an article entitled "Spatial-spatial planning and organization of health and medical services using GIS case: Zanjan city" found that in most cities there is a lack of appropriate allocation of space and optimal placement of service and physical elements. The city, especially the medical centers (hospitals) and the number of effective factors in the location of these centers, has followed and continues to increase the problems of the city and its citizens. Therefore, this has revealed the necessity of using effective methods and computer systems in the optimal location of these centers. The current location of most of the medical centers and hospitals in Zanjan city does not match the scientific criteria of the needs of this land use, at the same time, the findings of this analysis show that the current need of medical centers in Zanjan city is at least 7 hospitals according to the city's per capita, which the city officials They can use 11 points extracted from gis to solve this deficiency [48].

Rahnama and Amirfakhrian (2010) analyzed spatial access to healthcare services in the city of Mashhad. They stated that access planning, as a method of integrated planning of users and transportation networks, has two spatial and non-spatial dimensions. The availability and availability of services is one of the dimensions of spatial access, and this study examines medical services in Mashhad. The study method is of descriptive-analytical type, based on which, after forming a spatial data bank of therapeutic spaces in ARC-GIS software (including 6 major uses with 4528 frequency items) and using accessibility models. two-stage floating basin", the condition of Mashhad's districts' access index to each of the treatment spaces was determined. The advantage of using this method, compared to other methods, is the simultaneous use of indicators such as distance, functional radius, and number of facilities. The result of this analysis shows the mismatch between the spatial distribution of the population and the distribution of medical services. In other words, the central areas of the city have the best access and the peripheral areas have the weakest access to medical services. In the following, while using SPSS software and the "two-stage cluster analysis" model, 1266 population zones of Mashhad city were classified in terms of access to health care services. In this section, the results of the findings showed that the city of Mashhad can be classified into two clusters, including the first cluster with an average accessibility index of 3.24, including 2.3% of urban areas (areas with excellent access conditions) and the cluster The second one with an average accessibility index of 0.061 includes 97.7% of the domains, which does not show a good situation compared to the first cluster. The graphs prepared from the evaluation of this model showed that the most important indicator regarding the difference between the first cluster and the second cluster is the index of access to pharmacies. On the other hand, the index of access to emergency bases shows the least role in this classification [49].

Shojaiyan and Rahimpour (2017) in an article entitled "Evaluation of land suitability of health-treatment centers using CF analysis (case study: regions one and eight of Ahvaz city)" stated that the assessment of urban land suitability is the basis of urban planning. Especially in the field of proper use of land. This important issue directs the existing uses in the city in such a way as to prevent incorrect and incompatible adjacencies and ultimately lead to the establishment of land suitability. The present research was carried out with a descriptive-analytical approach in order to evaluate the land suitability of health-therapeutic centers in areas one and eight of Ahvaz city. ArcGIS software and CF relationship were used to achieve the mentioned goal and analyze the obtained information. Finally, the spatial distribution of land and the suitability percentage of each of the selected uses were determined with health-therapeutic use. The results of the research showed that among the uses studied, industrial use with 16.17%, residential use with 8.17%, and then fire stations with 7.53% had the highest incompatibility, and main roads with 0.71% had the lowest incompatibility. Is. In the end, 41.09% of the total area of the studied area is occupied by incompatible areas, 18.66% by neutral areas, and 13.02% by compatible areas. According to the conducted studies, the suitability of the land and the proximity of the selected uses in relation to the health-therapeutic use in the studied area have not been proportionately observed [50].

Motamedi (2019) in a research article entitled "Investigation and locating the access of the citizens of Shirvan city" to therapeutic uses. In this article, one of the basic and important tasks of urban and regional planners is to allocate land to various urban uses while paying attention to the role and function of the city, the economy of the city, and also the effect of mutual factors of uses on each other. The results showed that in terms of location, the studied clinics are concentrated in the eastern side of the city, and the central and western parts of the city are limited in terms of access to the clinics, and only 28,136 people out of the city's population of 83,000 have access to the standard radius range of the clinics; In other words, it can be said that about 75% of the city's population is outside the standard radius of the clinics, and the access radius of the clinics is not suitable for the citizens of the city, and there is a need for a well-equipped hospital in the west of Shirvan [51].

Hataminejad et al (2017) in a research entitled "Analysis of access to urban services in Esfrain" which was conducted using a questionnaire and unbalanced Morris index, concluded that the upper socio-economic classes in the city of Esfrain, in terms of having better financial conditions, they have more favorable uses, and the distribution pattern of service uses is in favor of more prosperous groups so that it is not consistent with the concepts of social justice [52].

Rostami (2010) in the research "Investigation and analysis of urban public service distribution from the perspective of spatial justice, case study: Yasouj city" the degree of access and need of residents to public services using the access network analysis model, hierarchical analysis model and analysis model local spatial autocorrelation has been investigated and analyzed. He also used the Gini coefficient to analyze the inequality of access to urban services and the Moran coefficient to analyze the pattern of distribution of injustices among urban blocks and finally concluded that urban public services are based on accessibility, public benefit, efficiency Population distribution and residents' needs for public services have not been fair and facilities are concentrated in certain areas [53].

Rahnama and Zabihi (2011) analyzed the distribution of public facilities in line with spatial justice with the integrated model of access in Mashhad in 2013 and in this research they concluded that the integrated access analysis of services with the help of geographic information system and spatial autocorrelation technique This indicates that the spatial distribution of public facilities based on Moran's index is clustered and based on the general index, it is a cluster with low concentration. The final result is that the spatial distribution of public facilities is not fair based on the integrated model [54].

CONCLUSIONS

The range of topics and topics of strategic urban research is very wide. For example, studying sports, recreational, therapeutic, educational spaces, police stations, fire stations, etc. All of them are topics that the researcher can investigate. To scientifically and accurately examine urban issues, it is necessary to carefully examine the components and influencing factors according to their type and degree of importance. In addition, due to the rapid growth and expansion of cities, the existence of a multitude of variables affecting them, as well as the incredible amount of information, the use of traditional methods in the analysis of problems is not very reasonable and expressive, and it is misleading. Factors such as population growth, migration and its consequences, and the fair and optimal distribution of services in the city environment and especially the metropolises are associated with obstacles and problems, therefore, adopting efficient and appropriate policies in relation to the provision of services and optimal allocation of space for the population living in different sectors of the city (outskirts, center, etc.) is one of the important goals of urban planning for quick and low-cost access to citizens. In this chapter, theories and models such as spatial allocation models, access models, attraction models, therapeutic approaches, sustainable development theory, and spatial theories were discussed.

Therefore, considering the problems stated above and the large spatial scale and analysis of a large amount of mechano-descriptive and statistical information, the researcher was motivated to solve various problems by having analytical functions (especially network analysis facilities, spatial allocation models and modeling in general) including analysis of accesses, determination of sphere of influence, location, and allocation of resources, sustainable development, development of social justice and so on.

With the help of these tools and statistical analysis, reach scientific results. Biological accidents and threats, re-emerging, and emerging diseases are increasing, and in these diseases, accidents, and threats, the first place to get involved is the Ministry of Health, especially hospitals. Hospitals must have the necessary preparation to face these incidents and threats so that in case of such incidents, they have the least vulnerability reduce casualties, and can provide the best and safest care to clients. One of the ways to create readiness is to conduct exercises and maneuvers, therefore, for this purpose, hospitals must write and practice several scenarios regarding various types of accidents and biological threats.

REVIEW

Immunomodulatory Effects of Statins in the Treatment and Prophylaxis of Influenza Viruses

Abstract: *Background and aim: Influenza, commonly referred to as "the flu," is an infectious illness caused by influenza viruses (IV). Despite the availability of efficient antiviral drugs, the IV still significantly increases mortality. Antiviral drugs swiftly remove these viruses from pulmonary secretions, suggesting that a prolonged inflammatory response may be to blame for the poor result. Therefore, using immunomodulatory medications looks advantageous. Numerous anti-inflammatory effects are produced by statins. Numerous retrospective studies recommended that statins be considered for IV therapy. This study set out to comprehensively examine the immunomodulatory potential of statins in IV prophylaxis and therapy. Methods: From the beginning until 25 March 2022, a number of electronic databases (Scopus, EMBASE, PubMed, Web of Science, ProQuest, OVID, EBSCO, and CINAHL) were searched for cohort studies and randomized trials assessing the association between outcomes or risk of infections and statin therapy. Data were gathered on the investigated characteristics, measuring statin usage, quality evaluation, and results (set for potential confounders). Results: Finding additional therapeutic agents for influenza prevention and management is crucial since there are uncertain public health issues regarding the clinical efficacy of conventional medications. Pro-inflammatory cytokines are released as a result of influenza. According to the results, by using anti-inflammatory medications, severe influenza infections can be prevented along with pleiotropic effects. As a result, statins, which are cardioprotective medications with immunomodulatory and anti-inflammatory properties, may be beneficial for individuals with IV. Conclusion: Based on the positive immunomodulatory effects of statin administration, our systematic review's findings suggested that IVs may be prevented and treated.*

Keywords: *immunomodulation, antiviral, anti-inflammation, statin, prophylaxis, Influenza viruses*

INTRODUCTION

Despite the Influenza virus (IV) being recognized as a serious pathogen during the past century, influenza continues to cause a sizable number of ailments. According to estimates, only in the US in 2017–2018. (Table 1) [1].

Universally, The worldwide WHO estimates that each year, influenza epidemics cause 3,000,000–5,000,000 serious illnesses, with 290,000–650,000 recorded fatalities due to the severity of IV [2]. Although yearly influenza vaccinations are advised and antiviral drugs are available, both have a number of limitations. Following influenza infection, immunological dysregulation, which is determined to release the pro-inflammatory cytokines generating major risk factors for mortality and morbidity, is the cause of the severity of the disease and clinical presentations [3]. Tumor necrosis factor-alpha (TNF-α) and interleukin-6 (IL-6) are the most significant implicated cytokines, generating innate immune responses and inflammation [4]. The antigenic changes over time (requiring a precise strain match annually), vaccine strain egg-adapted changes, slow manufacturing processing, the absence of cross-reactivity, brief duration of protection, and poor immunogenicity in certain populations (for example, the elderly) all play a significant role in the effectiveness of the seasonal influenza vaccine [5,6]. If given at the right moment during the illness, antiviral medications such as neuraminidase inhibitors might have a profound effect; otherwise, they have only a subtle impact on clinical symptoms [7]. Prophylaxis is defined as a preventative measure against disease.

A preventative measure has immediate effects against response-triggering and can reduce the systemic reaction to physiological stress or illness. This development might greatly reduce the detrimental disease-related circumstances [8]. The most often given medications in the world are statins, which decrease cholesterol. Statins block the enzyme 3-hydroxy-3-methyl glutaryl coenzyme-A reductase, which catalyzes the rate-restrictive step of cholesterol production. Statins have been shown to have positive cardiovascular benefits (Figure 2). [9].

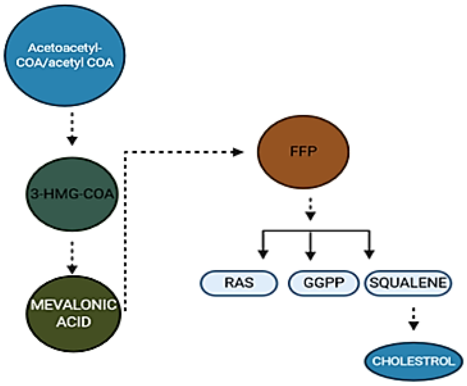

Figure 1: Statins' advantageous cardiovascular effects

Regardless of its effects on cholesterol levels, statins have been shown in clinical and experimental studies to decrease inflammation, improve endothelial function, and stabilize atherosclerotic plaques through a direct mechanism [10]. Statins can also alter cell shape, which is necessary for viral propagation [11]. Despite conflicting scientific findings, several retrospective observational analyses identified a link between statin use and decreased IV morbidity effects in people. However, these evaluations are constrained by the significant variation in medication delivery timing and duration across contributors or the participation of pneumonia morbidity in the absence of laboratory-approved IV infection [12]. A systematic review of statins' possible immunomodulatory properties in the treatment and prevention of IVs was the goal of this assessment.

METHODS

From the beginning until 25 March 2020, a number of electronic databases (Scopus, PubMed, EMBASE, Web of Science, ProQuest, OVID, EBSCO, and CINAHL) were searched for cohort studies and randomized trials exploring the connection between statin prescription and the result or risk of infections. Data on trial characteristics, statin consumption measurement, quality analysis, and outcomes were retrieved (set for potential confounders).

Influenza and the immune system

IVs are single-stranded RNAs that belong to the Orthomyxoviridae family and are divided into 4 categories based on their negative sense, segmented, and ssRNA genomes [12]. (classes of A, B, C, and D). In the meantime, many animal species might contract the influenza A virus (IAV) [13]. The IAV genome is almost 13,500 bases long and has 8 ribonucleoproteins (RNP) units, which together may encode at least 17 different proteins, including the recently identified

NS3, M42, PA-N155, and PA-N182 [14].

The genetic characteristics and molecular makeup of the neuraminidase (NA) and hemagglutinin (HA) proteins allow for further classification of IAVs. However, 9 NA and 16 HA subtypes were shown to be present in both human and animal bodies [15]. There have been reports linking many important IAV-encoded proteins to the host immune response and virus pathogenesis to the viral infection. According to research, changes in viral proteins' amino acid composition are linked to greater immune evasion and illness severity in humans and birds caused by IAVs [16]. In order for B cells to start producing neutralizing antibodies, HA contains epitopes. Therefore, the primary factors influencing recombination processes and viral mutation are the HA epitopes [17]. An innate immune response is the initial line of defense for the body against viral infection. IAV replicates itself by concentrating on respiratory tract epithelial cells. Understanding the innate immune systems defending these cells against IAV infection is crucial. Pathogen-associated molecular patterns (PAMPs), which are present in airway epithelial cells, are identified by receptors such Toll-like receptor (TLR) 3, melanoma differentiation-associated protein 5 (MDA5), and retinoic acid-inducible gene I (RIGI) [18]. Different autocrine signaling pathways can trigger the production of class 1 and 3 interferons (IFNs) and other cytokines instead of locating PAMP [19]. IFN lambda receptor 1 (IFNLR1-IL10R2) and IFN alpha/beta receptor (IFNAR1-IFNAR2), which are the receptors for class 1 and class 3 IFNs, respectively, can result in the paracrine response, which in turn activates a number of ISGs with antiviral activity and, as a result, induces the defensive activity of neighboring cells against viral infection [20]. The majority of adaptive immunity against IAV infection comes from B and T cells. T lymphocytes are mostly recognized as CD8+ and CD4+. In order to create cytokines and other powerful chemicals that can stop viral replication and kill virus-infected cells, CD8+ T cells are developed into cytotoxic T lymphocytes (CTLs). T cells are therefore essential to limit viral infection [21]. The naive CD8+ T cells are stimulated by the DCs to go from the lungs to the draining lymph nodes' T-cell zone during IAV infection, where they differentiate and multiply into CTLs [22]. Additionally, IL-12, IL-2, class 1 IFN-, and IFNs help to differentiate CD8+ T cells into CTLs [23]. It has also been demonstrated that IFN- increases T-cell proliferation during IV [24]. The workings of CTL have been extensively studied. The CTLs create cytotoxic granules that contain chemicals like granzymes and perforin while the virus targets the cells [25]. Additionally, CTLs can activate death receptors in IAV-infected cells by secreting cytokines including TNF, TRAIL, and FASL [26]. Following infection, lymphoid organs, blood, and the infection site are circulated with virus-specific DCs and CTLs [27]. The differentiation and activation process during the first infection increases the memory CTL cells' effectiveness and proficiency in secondary infection, and the memory CTL cells respond swiftly to subsequent IAV infection [28]. Although neutralizing antibodies are protected from subsequent infection with the same IAV serotype, CTLs are epitope-specific in conserved IAV proteins including NP, PA, and M1. As a result, the CTL response is heterosubtypic [29]. CD4+ T cells are a crucial subset of immune cells that are involved in adaptive immunity against IAV infection. In mouse models, CD4+ T lymphocytes may promote MHC type 2 expression in epithelial cells and target IAV-infected epithelial cells [20]. The CD40 ligand (CD40L) is notable among the several co-stimulatory ligands produced by CD4+ T cells that are important in antibody production and B cell activation [21]. TNF, IL-2, and IFN- are examples of antiviral cytokines generated by Th1 effector CD4+ T cells that activate alveolar macrophages [22]. IFN- and IL-2 released by Th1 cells control CD8+ T-cell differentiation to clear viral infection [23]. Additionally, CD4+ T cells can develop into killer, Th17, Th2, follicular helper, regulatory, and rarely Th2 cells [24]. Antigen-offering cells attach to MHC type II-related peptides produced from viruses, and Th2 cells produce IL-13 and IL-4 primarily to encourage B cell responses [25]. It was discovered that the control of cellular immunity against IAV infection includes the Treg and Th17 cells.

Immunopathogenesis of Influenza

The primary targets of IV for infection are respiratory epithelial cells, which are also amplified cytokines by the choreographers [26]. Following first exposure, the offspring viruses that have multiplied inside of these cells can spread to other cell types, including alveolar macrophages. The inflammatory reactions start when infected cells die through necrosis or apoptosis [27]; acute inflammation is thought to be the body's main defense mechanism against damaging stimuli. In order for leukocytes and plasma to reach the site of extra-vascular injury, blood flow must be increased. Acute inflammation is identified by an increase in local temperatures and discomfort [3]. Acute inflammation is indicated by the activation of pro-inflammatory chemokines or cytokines [28]. Inflammatory cell recruitment may happen as a result of these pro-inflammatory chemokines or cytokines. Then, there is extensive tissue damage, immune cell infiltration, and a gradual expression of antiviral, inflammatory, and apoptotic genes [29]. Both the repair of the damage and the regeneration processes begin at the same time. Most of the time, this repair technique can fully restore the function [30].

The formation of hyaline membranes, diffuse alveolar damage, fibrotic healing, and fibrin exudate (Figure 3), which are thought to be signs of severe capillary damage, persistent organ dysfunction, and immunopathologic injury, are among the more pathologically severe alterations found for severe inflammation related to cytokine storm. Additionally, the release of strong inflammatory chemokines and cytokines into the bloodstream can result in systemic cytokine storms and multiple organ failure [32].

Cytokine Storm
① Influenza virus infects lung cells
② Immune cells, including macrophages, identify the virus and produce cytokines
③ Cytokines attract more immune cells, such as white blood cells, which in turn produce more cytokines, creating a cycle of inflammation that damages the lung cells
④ Damage can occur through the formation of fibrin
⑤ Weakened blood vessels allow fluid to seep in and fill the lung cavities, leading to respiratory failure

Figure 2: Severe inflammation related to cytokine storm

Because viral virulence and host resistance both have a role in the severity of influenza outcomes, it is imperative to use immunomodulatory treatment in addition to traditional antiviral medication. Indeed, several studies have shown that administering immunomodulatory medicines, with or without antiviral medications, can reduce organ damage and death from severe influenza. Additionally, the majority of these medications are not costly and are made simply, making them potentially useful in large-scale influenza pandemics. Here, the characteristics of statins and some instances of these were discussed.

Statins as immunomodulatory agents

The enzyme hydroxyl methylglutaryl-coenzyme A (HMG-CoA) reductase is inhibited by statins. By catalyzing the reduction of HMG-CoA for mevalonate during cholesterol synthesis, this enzyme can gauge the pace of the early step of the cholesterol biosynthesis pathway [33]. In addition to their ability to lower cholesterol levels, statins are pleiotropic cardioprotective medications that are gradually becoming recognized as direct cellular effect mediators. Statins inhibit downstream molecules, which are essential for viral contagiousness [34]. They reduce or prevent the production of downstream isoprenoid intermediates such as farnesyl pyrophosphate and geranylgeranyl pyrophosphate (GGPP) (FPP). These isoprenoid intermediates interact with membranes when post-translational proteins are modified. Statins regulate GDP and GTP-bound states by controlling their isoprenylation and preventing them from switching from the cytosol to the membrane when they are inactive [35].

Figure 3: Some functions of statins

As a result, statins stop the activity and membrane translocation of isoprenoid intermediates and reduce their production. It is thought that lowering the isoprenylation of several proteins mediates the pleiotropic effects of statins.

This is best shown by the Rho GTPase family, which includes RhoA, Cdc42, and Rac, and which performs distinct roles dependent on the shape, secretion, motility, control, and proliferation of gene expression in cells [36]. To apply their activities and membrane interactions, members of the Ras family must add a farnesyl group to processes such as platelet activation, cell division, differentiation, intracellular vesicle transport, and the production of oxygen radicals [37]. These effects of statins include immunomodulatory actions such as the reduction of T-cell activation, the inhibition of inflammatory responses in neutrophils and macrophages, and the inhibition of a number of pro-inflammatory cytokines like TNF, IL6, and IL8. Furthermore, it has been demonstrated that blocking MAPK pathways such p38 MAPK, JNK, and ERK1/2 prevented the expression of RANKL, the production of cytokines and MMPs, and the degeneration of cartilage in different cells from RA patients (Figure 3). [38-42]

Use of immunomodulatory features of statins on IV treatment

According to three categories, including in vitro, human, and animal investigations, the effects of statin-related immune-modulation were examined to treat influenza in a number of studies. The following sections were used to review particular research from each category.

In vitro study

In the US Vaccine Effectiveness Network trial across 6 influenza courses (2011-2012 to 2016-2017), Havers et al. evaluated the influenza VE in statin users and nonusers with age higher than 45. All individuals with acute respiratory illnesses were screened for influenza at outpatient clinics. According to the data, out of 11692 eligible contributors, 3359 (30%) used statins, and 2806 (24%) tested positive for IV illness. Meanwhile, only 60% of nonusers and 78% of statin users obtained influenza vaccination. Setting for possible confounders came in at 39 percent (95 percent CI, 32 percent -45 percent) among nonusers and 22 percent (95 percent confidence interval [CI], 22 percent -47 percent) among statin users, with influenza VE coming in at 36 percent. They discovered no appreciable VE alteration as a result of statin use. Between nonusers and statin users, VE against influenza A(H3N2), A(H1N1) pdm09, and B viruses were comparable. When they analyzed the data by type and subtype, they discovered that the use of statin administration did not change the effect of vaccination on influenza [43].

According to research by Gower et al., lovastatin can stop virally induced cell-to-cell fusion and RSV replication. The experimental research showed that isoprenylation inhibition is a potential new antiviral strategy for treating or preventing severe RSV infection [44]. Statins, a widely used and affordable pharmacological medication, may be effective in preventing current and future influenza epidemics, particularly in less developed and underdeveloped nations, according to Mehrbod et al. By lowering cytokine over-expression and modulating strong inflammatory responses, statin therapy may protect the body from inflammatory reactions in the pulmonary system and other inflammatory reactions connected to severe influenza sickness. The availability of statins, which might be used as preventative or supplemental drugs to lessen the severity of the disease, and possible preventive medical therapy for unanticipated pandemics, may help to diminish the inflammatory repercussions of influenza that are connected with it [45]. Simvastatin and H1N1 elevated membrane localization and LC3 protein lipidation, according to Mehrbod et al. Simvastatin, however, has a direct influence on LC3 lipidation through a reduction in cholesterol, while H1N1's contribution to autophagy is more convoluted due to its effects on the activation of several autophagy-related genes to boost the autophagic flux. Their results were in line with those of an earlier study on the primary human lung mesenchymal cells, highlighting the relationship between the relative amount of LC3-II and the dynamic turnover of LC3-II through lysosome activity [46].

Animal study

Despite the ambiguous results, several animal studies showed that alternative statin medications may be protective against acute lung damage. In C57BL/6 mice infected by IAV, Haidari et al. observed that atorvastatin (40 mg/kg/day) prescription decreased the lung viral titers and mortality. Statins work directly against influenza by inhibiting the Rho/Rho-kinase pathway. The statins' protection against influenza might be viewed as a component of their cardiovascular event prevention benefits [47]. According to Lee et al., the treatment of simvastatin plus the neutralizing RANTES antibody effectively inhibited the growth of neutrophils caused by poly I:C in the lungs. Additionally, they said that simvastatin inhibits neutrophilia in poly I:C-induced pneumonia by inhibiting STAT3-mediated RANTES production. Understanding the etiology of viral pneumonia is crucial in order to develop effective anti-inflammatory or antiviral medications for certain inflammatory conditions. Simvastatin should be considered as a potential therapeutic option for viral pneumonia, particularly in neutrophilic inflammation due to a viral component, they further said. Simvastatin can reduce airway inflammation, but its exact mechanism of action has to be understood [48]. Simvastatin's efficacy against influenza A/PR/8/34 virus infection in the mouse model was evaluated by Glück et al. The first trial used oral administration of simvastatin. In a subsequent investigation, intraperitoneal administration was used to achieve high plasma levels. Bodyweight loss, survival rate, histologic lung damage, and viral titers in the lungs and trachea were evaluated. Surprisingly, simvastatin treatment caused the mice to lose more body mass and have lower survival rates than the virus-infected control animals. Simvastatin also did not affect histological lesions, tracheas, or lung viral loads. In general, they demonstrated that simvastatin did not shield the mice from IV infection [49]. According to Radigan et al., rosuvastatin treatment did not successfully treat influenza A illness. Inflammation of the lungs, lung damage, and the degree of weight loss were comparable in rosuvastatin- and control-treated mice. Rosuvastatin treatment had no impact on mortality in influenza A-infected mice (A/WSN/33) Statins did not affect influenza A replication in vitro or its removal from the lung in vivo. Statins did not affect influenza A-related mortality and did not lessen the severity of the lung damage caused by the virus. According to them, there is no connection between HMG CoA reductase inhibitors and improved outcomes for patients with sepsis and pneumonia related to their effects on influenza A infection [50].

Human study

In critically ill patients with severe sepsis, Kruger et al. investigated the clinical and biochemical effects of atorvastatin treatment. Before using statins, the site stratified a phase II, prospective, multicenter, double-blind, randomized, and placebo-controlled experiment. A matching placebo or atorvastatin was given to 250 individuals in a cohort trial who had severe sepsis and acute infection (127 received placebos, 123 received statins) (20 mg daily). The results showed no interactions between treatment groups, showing that there were distinct behaviors across the groups throughout time (P = 0.26), and no variations in IL-6 concentrations (initial endpoint) between the placebo and atorvastatin groups (P = 0.76). The baseline IL-6 plasma titer was decreased (129 [87-191] vs. 244 [187-317] pg/ml; P = 0.01) in those who had previously taken statins. There was no difference between the two groups in terms of the length of hospital stays, hospital discharges at 28 or 90 days (15% vs. 19%), changes in Sequential Organ Failure Assessment scores, death at intensive care unit release, or negative effects. Patients on atorvastatin had reduced cholesterol (2.6 [0.06] vs. 2.4 [0.07] mmol/L; P = 0.006). Greater than 28-day mortality was detected for those randomly assigned to the placebo (28 percent vs. 5 percent; P = 0.01) than for those getting atorvastatin in the selected group of 77 past statin users. At 90 days, there were no statistically significant differences (11 percent vs. 28 percent; P = 0.06). A therapy with atorvastatin for severe sepsis did not appear to have an impact on IL-6 levels. A lower baseline IL-6 concentration in this population was associated with improved survival, while prior statin usage was associated with the continuation of atorvastatin [51].

According to Papazian et al., simvastatin (60 mg) prescriptions for supplementary VAP therapy did not lower day-28 mortality. Simvastatin did not substantially worsen any side effects. Although the superiority of a placebo to simvastatin was not tested in our investigation, it is important to note that day-28 mortality in the simvastatin group increased by approximately 6% absolute and by almost 8% absolute in the statin-naive category. It would be pertinent to look at the potential supremacy of a placebo over a statin as normal practice does not involve de novo statin administration in ICU patients with infection. They thus investigated the claim that simvastatin is preferable to a placebo. The results did not support the use of supplementary statin medication in ICU patients with VAP. Therefore, this result may be extended to ICU patients who have any type of nosocomial infection [52].

With the aid of connected administrative databases, Kwong et al. conducted a population-based cohort analysis across 10 influenza seasons (1996–2006) in Ontario, Canada. Before the start of the influenza season, they identified all persons over the age of 65 who had had an influenza vaccination, and they also separated those who had received prescription statins (23 percent) from those who had not (77 percent). A final cohort of 2,240,638 patients—exactly half of those taking statins—was obtained by matching based on propensity, which took into consideration each patient's likelihood of receiving a statin. Statins had poor protective effects against pneumonia hospitalization (odds ratio [OR] 0.92; 95 percent confidence interval [CI] 0.89-0.95), all-cause mortality (0.87; 95 percent CI 0.84-0.89), and pneumonia mortality within 30 days (0.84; 95 percent CI 0.77-0.91). The significantly decreased with time, varied between risk groups and propensity score quintiles, and remained unaltered across post-influenza season periods after multivariate regulation and while omitting multiple clarifications for each individual. They suggested that statin use could have a statistically significant, but little, protective effect on influenza morbidity, which was merely attributable to public health authorities and residual confounding. Additionally, doctors must focus on minimizing mortality and morbidity from the ensuing influenza epidemic [53].

CONCLUSIONS

The immunomodulatory effects of statins are mediated by a number of mechanisms, including direct activation of heme oxygenase and inhibition of major histocompatibility type II complexes, which interfere with the interaction between leukocytes and endothelium. The most crucial mechanism is intracellular inflammatory signaling, however. GTP-binding proteins serve as molecular on/off switches for various protein kinases, which makes them essential for intracellular inflammatory signaling. Both the cycle's inactive and active stages require isoprenylation for the route to be activated. By blocking 3-hydroxy-3-methylglutaryl-CoA reductase, statins lessen but do not completely abolish protein isoprenylation. The response strength of the impacted signaling pathway is decreased by this drop in prenylated protein concentration. As a result, it could balance out the "cytokine storm" associated with IVs. Based on the aforementioned effects, statins were found to have direct antiviral effects in some cases when used at physiologically appropriate concentrations. This suggests that they may prove to be an effective adjuvant treatment in the fight against pandemic and seasonal influenza, particularly in health systems that cannot afford expensive vaccines or antiviral medications. Despite conflicting results from several research, statins are affordable and easily available medicines in underdeveloped nations. By controlling immune system cytokine overexpression and modulating severe inflammatory reactions, they may be used as preventative medication or therapy for influenza sickness.

Abstract: *Background: Duct to mucosa Pancreatico-gastrostomy (DMPG) is a method for reconstruction of pancreatic mass following pancreaticoduodenectomy (PD). There are still controversies about the benefits of this surgical technique compared to the old ones. Objectives: This study aimed to evaluate the long-term outcomes of DMPG reconstruction following PD operation. Method: Through a prospective observational setting, 164 patients, undergoing PD surgery, with diagnosed pancreatic head or peri-ampullary cancer, were enrolled. A pylorus-preserving PD and DMPG were done for all patients to reconstruct the pancreatic mass. Patients were followed up to a mean of 21.06±14.12 months. Demographic data, risk factors, tumoral staging, and postoperative follow-up data were collected for the analytic study. Results: The mean survival of the patients was 21.06±14.23 months after surgery. DGE (delayed gastric emptying) (34.75%), pancreatic fistula (21.34%), bile duct fistula (7.31%), and hemorrhage (5.5%) were recorded as the most important complication in patients. Some post-operative complications were significantly observed in patients with diabetes mellitus (pancreatic fistula, increased amylase, and DGE), Smokers (bile duct fistula, hemorrhage, and increased Amylase), and the elders (bile duct fistula) (p-value <0.05). Conclusions: Although our results indicate that DMPG reconstruction is a safe technique, our findings did not confirm the priority of this method over the older techniques.*

Keywords: *pancreatic neoplasms, gastrostomy, jejunostomy, pancreaticoduodenectomy*

INTRODUCTION

Pancreaticoduodenectomy (PD) is the main surgical treatment option for ampullary and peri-ampullary cancers, and some modifications have been described for this surgical operation. Therefore, these surgical modifications, complications, and outcomes need to be evaluated.

Despite the surgical techniques and management improvements, there are still many concerns about its high incidence of post-operative complications and morbidity rate (30-50%) [1,2]. Pancreatic fistula is considered the most common postoperative complication followed by bile duct fistula, thromboembolism, intra-abdominal hemorrhage, intra-abdominal abscess, wound infection, and gastro-intestinal bleeding as other important complications [2].

Reconstruction with pancreaticojejunostomy (PJ) is the preferred anastomosis technique following PD surgery. While this method has been commonly used for several decades, its high prevalence of complications (40-50%) prompts surgeons to come up with new approaches [3-5].

Duct to mucosa pancreaticogastrostomy (DMPG) is a method of reconstruction following PD surgery. There are still controversies about its benefits compared to previous ones. Few studies are available evaluating DMPG's outcomes, and complications [6-8]. This study aimed to evaluate the long-term outcomes of DMPG reconstruction following PD operation.

MATERIALS AND METHODS

Patients

In this prospective observational study, patients with the diagnosis of pancreatic head or peri-ampullary tumors who underwent PD surgery at Baqiyatallah Hospital from January 2007 to February 2016 were enrolled. Informed consent was taken from patients. All operations were performed by the same surgeon. Patients were excluded from the study if failed to follow or their data were incomplete or inaccessible. Altogether 191 patients were included. During the study, 27 patients were excluded, (12, due to changes in their address, and 15, because of incomplete data and/or failure to follow). The study was approved by the ethics committee of Baqiyatallah University of Medical Sciences (national approval number: IR.BMSU.REC.1393.87).

Surgical Procedure

In all operations, a right subcostal incision was made and a pylorus-preserving PD and DMPG (using 4-0 polydioxanone sutures) were performed for the reconstruction. The Head of the pancreas was transected with at least a 2 cm macroscopic surgical margin from the mass, usually at the margin of the head and neck of the pancreas. The proximal duodenum was transected about 1.5-2 cm distal to the pylorus.

During the DMPG reconstruction, a small piece of the feeding tube was inserted into the DMPG anastomosis, like a stent, to secure the patency of the anastomosis within the first few days. The tube was not fixed with sutures. An end-to-side duodeno-jejunostomy hand-sewn anastomosis was made using 3-0 vicryl sutures. The coledoco-jejunostomy anastomosis was created about 50 cm distal to duodeno-jejunostomy using 3-0 Vicryl sutures. Tumor Lymphadenectomy was performed in all patients with palpable regional lymph nodes. A Penrose drain was inserted in the bed of the surgical site, and a closed-suction drain was placed in the Morison pouch.

Data Collection

Demographic information including age, sex, risk factors for the disease and surgery, history and laboratory, data essential to calculate the American Society of Anesthesiology scoring (ASA) class, and clinical staging of the tumor were collected and recorded into a checklist before surgery.

Duration of the operation, length of stay (LOS) in the hospital, post-operative complications, short- and long-term outcomes, pathologic result of the sample, morbidity, and mortality were recorded into the checklist during close follow-up. The patients were followed up to a maximum of 11 years or up to the date of death. The post-operative complications include pancreatic fistula, bile fistula, thromboembolic events, intra-abdominal fluid collection such as hemorrhage and abscess, wound infection, gastrointestinal bleeding, and gastroparesis. International Study Group on Pancreatic Fistulas (ISGPF) criteria was used to estimate pancreatic fistula [9]. Delayed gastric emptying (DGE) was graded according to the validated criteria of the ISGPF classification [10]. Pre-operative ASA classification was also assessed according to the ASA classification of physical status [11].

Statistical analysis

Data were analyzed using IBM SPSS Statistics for Windows (version 21, IBM Corp, NY). Averages were expressed as mean ± SD. Kolmogorov-Smirnov test was used to assess the normal distribution of data. Possible statistical relationships between the risk factors and complications after the surgery were calculated using student t-test, ANOVA, and Chi-Square tests. The p-values equal to or less than 0.05 were defined as statistical significance levels.

RESULTS

In this study, a total of 164 patients with a mean age of 62.21± 9.34 years (including 93 males and 71 females) were included. The demographic information, risk factors, and also the number of cases in each ASA class are demonstrated in Table 1. Most of the patients were in class II of ASA classification (45.73%). According to the exclusion criteria, the patients with class V of ASA classification were excluded from the study.

Table 1: Demographic information, risk factors, and ASA class of patients

Variable (N=164)		
Age, (Mean± SD)	62.21 ± 9.34

DM: Diabetes Mellitus, IHD: Ischemic Heart Disease, ASA: American Society of Anesthesiology scoring

Adenocarcinoma was the most prevalent tumoral type in this study (41.46%). Less common pathologies were cholangiocarcinoma, ampullary carcinoma, high-grade dysplasia, neuroendocrine carcinoma, and intraductal papillary mucinous neoplasm (IPMN). The mean pancreatic duct size was 4±1 millimeters. According to the TNM tumoral staging, 55 (33.5%), 70 (42.7%), and 39 (23.8%) of tumors were classified as T1, T2, and T3, respectively.

Post-operative data such as complications, mortality rate, and their relationship with the risk factors are illustrated in Table 2. In brief, DGE (delayed gastric emptying) (34.75%), pancreatic fistula (21.34%), bile duct fistula (7.31%), and hemorrhage (5.5%) were recorded as the most important post-operative complications in patients. Some post-operative complications were significantly observed in patients with diabetes mellitus [pancreatic fistula (p-value 0.038), increased amylase (p-value 0.010) and DGE (p-value 0.024)], smokers [bile duct fistula (p-value 0.027), hemorrhage (p-value 0.026) and increased amylase (p-value 0.045)] and the elders [bile duct fistula (p-value 0.006)]. No patient reported a history of alcohol consumption as a risk factor for pancreatic cancers.

[a]: *Significant increasing amylase = triple time level for more than 3 days*

[b]: *Surgical resection margins were not restricted to malignant tumors, and the surgeon had to conduct more resection to reach a free margin*

*The character * in the above P values indicates that there is a significant statistical relationship between the two methods of surgery*

The mean follow-up time of the patients was about 21.06±14.12 months. The mean survival of the patients was 21.06±14.23 months after surgery. There were 5 early post-operative mortality; one case due to massive lung embolism, three because of post-operative intra-abdominal hemorrhage, and one patient due to myocardial infarction. The survival rate of patients who were diagnosed with adenocarcinoma was 19.93±15.02 months. Survival rates for other groups are shown in Table 3. Also, the mean survival years in each pathologic type of tumor are shown in Figure 1. The longest survival is seen in non-malignant masses and the shortest survival is seen in PMN tumors.

DISCUSSION

Pancreaticoduodenectomy is an accepted surgical treatment for pancreatic head and peri-ampullary cancers. However, its complications have made surgeons find a better surgical technique in recent years [12].

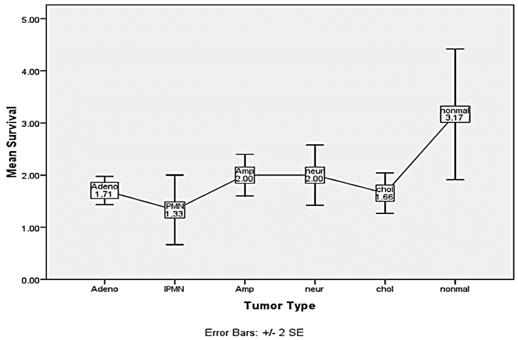

Figure 1: Mean survival year of the patients for each tumor type (*Adeno: Adenocarcinoma, IPMN: Intraductal papillary mucinous neoplasm, Amp: Ampullary Carcinomacarcinoma, Neur: Neuroendocrine tumor, Chol: Cholangiocarcinoma*)

PJ reconstruction is one of the accepted and common methods of anastomosis after the excision of the pancreatic head and duodenum. However, the current method has many challenges such as a high rate of postoperative pancreatic fistula (POPF) and abdominal collections that are reported to be decreased in PG reconstruction in comparison to PJ reconstructions in different studies [13].

Table 3: The patients' survival rate (±SE); according to the pathologic type of tumor

Tumor Survival	Ade (%)	IPMN (%)	Amp-Car (%)	Neur (%)	Chol (%)	Non-mal (%)	Total (%)

Duct to mucosa pancreatico-gastrostomy anastomosis is a method of anastomosis following PD surgery. There are few studies to show the distribution of complication rates after the DMPG surgical technique [7].

There are many accepted risk factors for POPF. Many risk factors are related to the pancreas itself and are different among patients; these include the size of the duct, histologic features, and the blood supply of the tail. However, many risk factors are related to the techniques of surgery such as anastomosis type after PD, stenting of the anastomosis, and blood loss during surgery [5,7,14].

In this study, there was also a significant relationship between the history of diabetes mellitus and the development of POPF (P=0.038). In a previous study, the risk of POPF was significantly higher in patients with diabetes mellitus (P=0.03). There was no significant relationship between age and POPF (P=0.69). Our finding in this regard is different from other studies [15]. Amylase levels and delayed gastric emptying (DGE) in diabetic patients were higher than in other patients.

In most studies, the male gender has a strong risk factor for pancreatic cancers. In our study, 56.7% of patients were male. However, gender was not an important risk factor for complications after surgery, the rate of bile duct fistula was higher in the elders significantly (P=0.006).

Smoking is another major risk factor for pancreatic cancer. The actual mechanism of this process is unknown. However, cigarettes contain thousands of carcinogenic compounds that can cause cancers [16]. Smoking is also an important risk factor for complications after surgery as seen in our study smokers developed higher rates of bile duct fistula and hemorrhage after the surgery. In these patients, the increase in amylase level was also higher than in other patients (Table 2).

In the current study, the prevalence of POPF was higher than the similar study on DMPG (21.32% vs. 2.7%), and also higher compared with PG (pancreatico-gastrostomy) reconstruction [17]. Although have no justification for that, it seems that DMPG doesn't have any priority in this regard. There are few reports on the comparison between POPF rates following DMPG and PJ anastomosis (21.32% vs. 12.28 and 34.48%) [18, 19]. In other studies, some complication rates such as hemorrhage, bile duct fistula, DGE, and also LOS are higher in PG in comparison to PJ anastomosis [17,19].

In this study, the prevalence of DGE was 34.75% which is higher compared to another study [5]. It might be because of the pylorus-preserving surgery done for the patient; however, this finding is not in favor of the priority of DMPG (Table 4). The prevalence of hemorrhage as a life-threatening post-operation complication was lower in this study (5.5%). On the other hand, the prevalence of bile duct fistula after PG was higher than in other studies. (7.31%, Table 5).

We calculated the DMPG survival rate for the first time according to a recommendation for future researchers by Topal et al [17]. The Survival rate after a mean follow-up of 21.06±12 months was 21.06±14.23 months in our study [17]. Survival rates for all pathologic types were similar and ranged from 1.33-2 years except for non-malignant tumors which resulted in a higher mean survival of 3.17 years (Figure 1).

Although our results indicate that DMPG reconstruction is a safe technique following PD, the claimed lower rate of post-operative complications and lower hospital stay is still in question and needs further investigation. Compared to other studies and the prevalence of this condition, the number of patients in this study is acceptable, however, it had some limitations. We did not perform subgroup analysis based on duct diameter. Also, pancreatic remnant consistency was not documented after our operations. Results might also be influenced by the surgical technique used for PG here. Also, we did not compare outcomes after DMPG with PJ anastomosis as a control group.

CONCLUSIONS

This study with a rather large number of patients and long-term follow-up after DMPG showed a lower rate of many post-operative life-threatening complications such as hemorrhage. On the other hand, the prevalence of bile duct fistula after PG was higher than in other studies. Though our results indicate that

Duct-to-mucosa pancreatico-gastrostomy reconstruction is a safe technique following PD however, does not confirm the priority of this method over older techniques. However, this contradiction calls for more studies including clinical trials and metaanalysis to clear all obscure dimensions.

Abstract: *Background. Primary headaches are comprised of three big categories: migraines (with or without aura), the third most common and the 6th most disabling disease worldwide, tension-headaches, and trigeminal autonomic cephalalgias, each with different, complex, and not completely understood pathophysiological, clinical, and neuroimagistic characteristics. Structures like the brain stem, hippocampus, or hypothalamus have been depicted as being the main triggers of these types of headaches, which have a significant impact on the quality of life. Methods. We performed a broad literature review on primary headaches from January 2016 to June 2023, analyzing the latest scientific updates and emphasizing the pathophysiological and neuroimagistic characteristics. Results. We provide a concise review of the main neuroimaging studies that help in differential diagnosis between several types of primary headaches. Conclusions. It is difficult to approach the pathophysiology of these three primary headache categories. Keeping in mind that neuroimagistic methods are rapidly developing (especially in the MRI sphere), the most important endpoint of future studies will be to establish a reliable distinction system for all these types of cephalalgias, thus updating the protocols and guidelines. Currently, imaging studies are indicated only in certain circumstances.*

Keywords: *migraine; tension-type headache; pathophysiology; trigeminal autonomic cephalalgias; imaging studies; cluster headache; SUNCT; MRI; fMRI; SUNA*

INTRODUCTION

Headache is a recurrent and upsetting symptom in the neurological sphere, also being one of the most frequent ones, patients often present to the physician for it. Most of the studies suggested that more than 90% of the population has suffered from headaches at least once in their lives [1]. The diagnostic standard for headaches of any cause has been offered over the past two decades by ICHD since 2004 and today reaches the updated ICHD-3 [2]. This accounts for approximately 3% of emergency department admissions, but some authors have identified percentages as high as 8% [3,4]. It is important to emphasize that the repeated presentation of a patient to ED for the same symptoms significantly increases the costs associated with medical care. These recurrent presentations occur in approximately 10% of headache patients [3]. When a severe headache begins, patients present to the ED frightened by the thought of a serious condition. However, one study showed that of 3026 imaging studies of patients presenting to the emergency department, pathology was objectified by imaging in less than 3% of them [5].

Given the high prevalence of this type of neurologic symptomatology, clinicians must carefully consider the indication for imaging studies because they are expensive and usually do not provide the desired information to guide subsequent treatment. In addition, headaches can lead to absenteeism from school or work, increasing the indirect costs associated with pathology. In a recent study, workers with headaches were observed to have low productivity or, more rarely, to be absent from work for up to 7.5 days/month [6].

Headaches of a primary cause are set apart by the presence of headache without any underlying pathology. These are far more common than secondary headaches. For example, the prevalence of TTH is as high as 70% during a person's lifetime [7]. In the past, categorization of these pathologies has been difficult because symptoms vary from person to person, but also in the same individual over time [8]. Standardization of primary cause headaches has been achieved by the ICHD-3 classification, which divides primary headaches into migraine, both with aura or without it, tension-type headache (TTH), and cephalalgias which belong to the trigeminal autonomic sphere [2,9]. The mechanism of action of these pathologies is not yet known, but research is ongoing. In this paper, we propose to present the situations in which imaging studies are indicated.

MATERIALS AND METHODS

We reviewed the literature related to primary cause headaches by searching the Google Scholar and Pubmed English databases between 2000 and 2023 with keywords such as "headache", "cephalalgia", "imaging", "MRI", "primary", "migraine", "tension-type", "cluster", "trigeminal", "autonomic", or any logical combination of these terms. In the first stage, the retrieved studies were filtered by a title check to exclude duplicates and assess their relevance. After this first step, the outstanding studies were distributed evenly and randomly to the authors of this study, in the first phase by reviewing the abstract to determine relevance and later by studying the entire text. We have extracted relevant, basic information from these articles, but also important news that may change the paradigm of primary headaches.

RESULTS

Migraine

Migraine is a disabling disease, being the most prevalent type of primary headache, with 12-15% of the general population suffering from it [10,11]. Prevalence is different between males and females, and also it varies by the age group: interestingly, in children, puberty, this pathology is more common in boys. In young adults, it differs, being more usual in females, probably due to the hormonal changes they undergo [12]. Throughout life, the prevalence is 12-17% for women and 4-6% for men [13]. It manifests as moderate to severe headache episodes, usually unilateral, with mild to moderate cognitive deficit and cortical hyper-excitability manifestations such as phonophobia or photophobia, nausea, and vomiting. Two phases of migraine are described: the ictal phase, which occurs during a migraine attack, and the interictal phase, which occurs between two migraine attacks.

Up to 30% of patients with headaches accuse migraine attacks, and their frequency also influences cognitive deficits [14,15]. The ratio of men to women is 1:3. According to the ICHD-3, the main types of migraine are those without aura, those with aura, chronic-type migraine, complications of migraine, probable migraine, and episodic syndromes associated with migraine [16]. Migraine appears as a result of electrical abnormalities occurring in the brainstem, and vascular abnormalities in the cerebrum, and when we talk about migraine with aura, the result of cortical spreading depolarization [17].

The aura manifests most often as a visual aura (80-90% of cases), characterized by flashes of light in the simplest situations to scotomas or complex hallucinations [18].

Four phases of migraine have been described: the prodromal phase, in which the first warning symptoms appear (depression, fatigue, hunger, food cravings), which are most likely associated with dopaminergic activation and precede the headache by 2-48 hours [19]; the aura (which occurs in one-third of migraine patients) represents reversible neurological symptomatology that usually lasts about one hour and it usually manifests as sensory, verbal or motor symptoms. However, the visual ones are the most common. These changes come before the start of the cephalalgia [16,20]; headache is commonly on only one side of the head, having a progressively aggravating pattern at the beginning, being linked with autonomic symptoms like photophobia or phonophobia, or with symptoms like nausea, sickness-like condition or vomiting [20]; the postdromal phase, which is associated with a localized headache that is aggravated by movement, fatigue, or dizziness.

Migraine can be clinically assessed by structural MR imaging. For example, we now know that both aura and headache are mainly associated with vasoconstrictive changes in cerebral arteries and veins. Hypersensitivity in the region innervated primarily by cranial nerve V, but also in extracranial regions, causes allodynia when a normally painless stimulus becomes painful, such as wearing glasses or a light touch to the face.

MRI examinations are not routinely recommended in migraine patients without aura when preventive treatment is not necessary, and some authors recommend imaging studies when three lines of preventive treatment fail [21]. Another recent study emphasizes that imaging examinations are not needed in migraine patients without red flags [22]. In migraine patients with aura, no examinations are recommended in typical cases, and in the remaining ones, MRI or MRA of the brain is recommended to rule out vascular anomalies [21]. Cerebral MRI is also recommended for vascular comorbidities or headache onset after 50 years of age. MRI is not recommended for chronic migraine, especially if the history shows progressive worsening of headache with typical symptoms [21]. In patients with persistent aura, hospitalization, and diffusion-type imaging are mandatory to rule out cerebral ischemia.

Migraineurs are sensitive to olfactory stimuli. Up to 40% of them complain of headache exacerbation when exposed to strong, irritating, or sensitizing odors, even in the interictal phase, with studies demonstrating abnormal activation of the amygdala and insular cortex in the case of certain crises caused by odor stimuli [23,24]. On the other hand, other studies determining thermal stimulation showed unequal activation of certain areas between migraine patients and the control population, such as in the lentiform nucleus, parahippocampal gyrus, subthalamic nucleus, prefrontal cortex, or temporal lobe [25,26]. 40% of migraineurs report that their migraines are activated by strong light stimuli in the interictal phase, and 90% of them report that they suffer from photophobia in the ictal phase. Some studies demonstrate visual-nociceptive integration at the brainstem level [27].

Usually, imaging studies are not required in patients with a normal clinical examination who present with typical migraine symptoms according to the ICHD-3 definition [20,28]. To distinguish between patients who do not require additional imaging studies and patients with warning signs who do require imaging studies, the SNOOP algorithm is used successfully, as follows: S for systemic disease (e.g., infections, HIV), N for neurologic assessment (confusion, seizures, focal neurologic signs), O for onset (sudden onset, first episode after age of 50), O from other associated features (medications, toxins, trauma, association of headache with Valsalva maneuver), and P from previous episodes (or headache progression). The American College of Emergency Physicians 2019 (ACEP 2019) and American Academy of Neurology (AAN) guidelines recommend imaging studies only for warning signs that are not indicative of a common headache [29,30]. The American College of Radiology (ACR) emphasizes that clinical physicians should not perform repeated imaging studies when the headache is not complicated [31].

However, in migraine, deep white matter lesions (Figure 1A, T2, and FLAIR hyperintensities) are seen in 20-30% of MRI examinations, regardless of age or periventricular white matter lesions. Their exact pathophysiology is not known, but two theories have been mainly discussed: the theory of ischemia due to circulatory disturbances in the small perforating vessels together with inflammatory changes with consequent hypoperfusion, evidenced in MRI imaging by the appearance of small focal ischemic spots, mainly at the level of the frontal lobe (Figure 1B), but also in the corpus callosum, and the theory of neuroinflammation [32,33]. The latter emerged after the CAMERA study, which highlighted in females that deep WML takes place without a connection with ischemic lesions [32]. It is noteworthy that numerous subsequent studies have highlighted the fact that in migraine, the deep supratentorial white matter lesions are important but these do not correlate with the development of the disease, whereas the infratentorial lesions do not affect migraine attacks [30]. In addition, migraine patients appear to have a higher risk for cerebrovascular disease, but also doubling the risk of ischemic stroke [34,35].

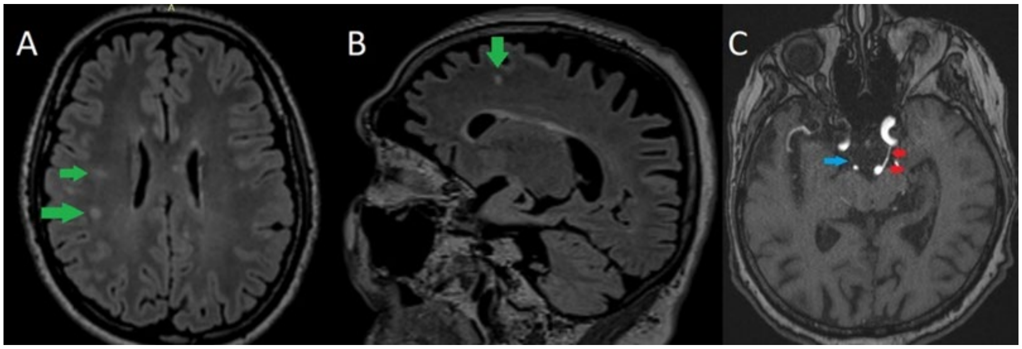

Figure 1: A: T2-weighted and FLAIR hyperintense lesions, in the centrum semiovale on the right side and deep white matter in a patient accusing repeated migraine attacks (green arrows). **B**: T2-weighted and FLAIR hyperintense lesion in the superior frontal gyrus (green arrow), the usual location for demyelinating lesions in migraine patients. **C**: asymmetry of the circle of Willis, showing a filiform right posterior communicating artery (blue arrow) compared to the contralateral one that shows significant blood flow (red arrows).

In migraine with aura, there may be transient restricted diffusion in the affected areas during the aura, in many studies taking place, especially in the corpus callosum [36].

Following some recent studies using MRI angiography (MRA), a new theory arises, advocating that there are asymmetries pointed out in the circle of Willis in a bigger population of migraine patients, particularly with aura (Figure 1C) [37,38].

In summary, in migraine patients without aura, imaging studies are not recommended for usual symptomatology that does not require treatment. For treatment-emergent migraine episodes, some authors recommend cerebral MRI or MRA when three lines of therapy have failed. In migraine patients with aura, an MRI of the brain is almost always recommended, or MRA if posterior fossa symptoms are present. In chronic migraine patients, additional imaging studies are not recommended as long as the symptomatology is not progressing, as long as the symptoms do not progress, but fundoscopy should be an integral part of the clinical examination in all patients with headaches [2,21].

Tension-type headache (TTH)

Tension-type headache represents a mild to moderate cephalalgia with a pressure-like character and usually occurs bilaterally, sometimes with anterior or posterior topography and sometimes it is longitudinal, lasting from minutes to days or even weeks. In contrast to migraine, it does not go along with autonomic manifestations or nausea and vomiting, and the presence of the above features precludes the diagnosis of tension-type headache. ICHD-3 classified TTH into four broad categories: infrequent epi-sodic TTH lasting < 1 day/month, frequent episodic TTH lasting 1-14 days/month throughout> 3 months, chronic TTH with a duration of > 14 days over > 3 months, and probable TTH [16]. The best diagnostic tool for tension-type headaches is the creation of a diary in which the patient records the frequency of painful episodes, their intensity, and their characteristics [39]. Considering the lower pain intensity, a lower proportion of patients with TTH consult a physician compared with migraine patients. One study has shown that the number of physician visits for TTH is 3 times lower than for migraine patients [40].

TTH is the second leading cause of chronic disease worldwide and is a socioeconomic burden, with 820 days missed from work or school per 1000 patients [41,42]. The most common differential diagnosis is migraine, as migraine patients often overlap with tension-type headaches.

The reported prevalence is 70% of the population, although 59% of patients report only episodic TTH [7,43]. Prevalence peaks in the 30-to-39-year-old age group and then decreases slightly [44]. Several studies have observed that sleep deprivation in combination with a disorganized lifestyle contributes to the occurrence of TTH [42,45].

Central factors are particularly important in tension-type headaches. While the pain threshold is normal in patients with eTTH, this threshold is somehow lower in tension-type headache patients with a chronic form [46,47]. Negative states, like depression or anxiety, and also chronic stress in TTH patients can increase the risk of headaches by lowering the nociceptive threshold [48,49].

In a study from Taiwan, it was suggested that the risk factors for TTH were more than 7 days of headache and female gender [50].

To date, although we use more and more advanced imaging techniques, the TTH pathophysiology is still not completely elucidated. Myofascial factors are incriminated to have a crucial role in episodic TTH along with pericranial muscle contractures, whereas sensitization of nociceptive sensory pathways by repetitive headaches leads to chronic TTH [51-53].

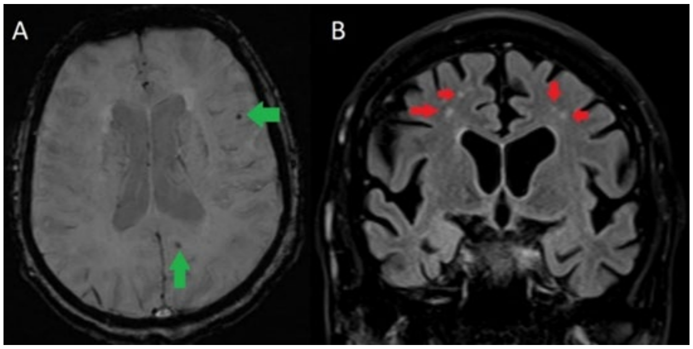

Figure 2: A. Magnetic susceptibility sequence in the axial plane. Changes in the magnetic susceptibility sequence with a suggestive appearance for microhemorrhages in the deep white matter and cortico-subcortical junction. **B**. Lesions in T2 and FLAIR hypersig-nal at the level of the bilateral corona radiata, in TTH patients without being specifically associated with some deep localizations such as in migraineurs.

As we already found out in the migraines chapter, imaging studies should not be carried out with typical-ly-described symptoms. More specifically, in patients with infrequent tension-type headaches, imaging is not recommended. In patients with frequent or chronic TTH, similar to migraine, some authors recommend an imaging examination when three lines of preventive treatment have failed [21]. Patients with chronic tension-type headaches should undergo one single imaging examination, either MR or CT, at the initial admission in the ED to exclude other differential diagnosis pathologies. The same applies to the TTH patients. The latter ones will generally have small foci of hemorrhage defined as hypodensities on susceptibility-weighted sequences deep in the white matter (Figure 2A) and deep WML, having the same physiopathological substrate as the migraineurs, increasing the risk of dementia or stroke later in life [54-56]. TTH and migraine patients generally have a similar number and amplitude of deep WML, but contrary to migraineurs, the TTH-associated WML does not show a preferred topography (Figure 2B). However, studies have shown that imaging examinations are not recommended because they do not improve the diagnosis and treatment, but they can cause and increase anxiety related to health status [57,58]. Acetaminophen and aspirin are thought to be efficient in cutting down acute symptomatology of hypertensive headaches. Opioids or triptans should be avoided. Ibuprofen and ketoprofen are the most effective NSAIDs for pain relief. Most patients benefit from lifestyle changes that promote a healthy lifestyle by quitting smoking and eating foods rich in antioxidants, and nonpharmacologic and behavioral therapies such as relaxation, biofeedback, or acupuncture can be helpful in most cases.

Trigeminal autonomic cephalalgias (TAC)

Cluster headache

Cluster headache is not a common headache, but is the most prevalent one in the group of TAC cephalalgias, having a prevalence of about 0,1% in the general population, affecting males and females differently, in a 6:1 manner. Many of the patients affected are older than 20 years of age [14,59]. Its most characteristics are severe pain with spontaneous remission, recurrent (usually circadian), unilateral, lasting 15-180 minutes, associated with autonomic ipsilateral cranial clinical signs such as lacrimation, conjunctival injection, or nasal congestion, the latter often leading to the misdiagnosis of sinus pain, with a completely different treatment from cluster headache [16,60]. In rare cases, cluster headaches may occur without autonomic symptoms [61].

80-90% of patients have episodic cluster headaches that occur apart from circadian development related to season (especially spring and autumn), number of daily light hours, and sleep stage, being more frequent during REM sleep [62]. Moreover, the relationship between sleep and cluster headache is very close. Many studies have shown that approximately 80% of patients who have manifestations of cluster headache will present cephalalgia attacks in the middle of the night, disturbing their sleep, but only 30% of them will show cephalalgias when they are napping during the day [63]. However, most of the patients complain of disturbed sleep quality, whether it occurs during or outside the headache period, and as a compensatory measure, some patients forget nightly sleep to avoid developing cephalalgic episodes [64]. An association between cluster headaches and sleep apnea has also been noted [63]. 10-20% of patients suffer from chronic cluster headaches, which have a very short period of remission, generally of the order of days.

The physiopathologic mechanism of this pain is not fully known. Both neurovascular causes and central mechanisms are suspected [65,66]. Given the predominant development with circadian recurrences, it has been suggested that the hypothalamus is of central importance for the development of pain, and also the trigeminovascular system and the parasympathetic systems being incriminated for starting and maintaining the symptomatology, those being involved in the autonomic trigeminal reflex [67]. Even though the V1 division of the 5th cranial nerve plays an important role in the development of algic symptoms, the autonomic ones are developed by the parasympathetic fibers of the facial nerve [68]. Since the 1990s, but also in more recent research, a genetic substrate is suspected, as there is a familial predisposition [69-71].

An association between cluster headaches and smoking has been confirmed. A recent study showed that 88% of the participating patients were active smokers or had smoked in the past [72]. When partial Horner syndrome occurs, cerebral MRI scans and targeted imaging studies at the level of the lung apex must be performed to identify lesions of the recurrent laryngeal nerve. Polysomnography may also be performed in cluster headache patients, as it is often associated with restless legs syndrome and helps to identify and treat this pathology [21].

In all types of TAC, cerebral MRI with high-resolution sequences of the cranial nerves is required at baseline to evaluate the parasellar structures. Similar to migraine, MRA is recommended if the first three lines of preventive treatment fail [21]. Changes in some brain structures were observed on imaging, particularly at the level of the thalamus, nucleus cinguli, prefrontal, parietal, and insular cortex [73,74]. Some older studies showed structural changes in the hypothalamus by MRI scans when headache was active, whereas other studies did not find these changes [75-77]. Some authors suggested that a decrease in grey matter volume in the visual cortex can occur, but it is non-specific [78,79].

Treatment of cluster headaches is divided into acute episode treatment and prophylactic treatment [80]. It includes drug treatment as well as patient education and lifestyle modification. As lifestyle changes, we can mention the avoidance of alcohol consumption, daytime sleep, or excessive physical activity. Treatment of the acute episode is initially by administering 100% oxygen by mask, up to 10 L/minute, for 15-20 minutes, which can relieve the cephalalgic episode in up to 15 minutes. Other therapeutic options include sumatriptan, a serotonin receptor agonist known to be the most effective therapeutic option and effective within 15 minutes when administered intravenously; dihydroergotamine, effective within 10 minutes when administered intravenously; zolmitriptan, effective within 30 minutes when administered orally; and local anesthetics [81]. Prophylactic treatment consists mainly of prednisone, dexamethasone, and ergotamine derivatives.

SUNCT and SUNA

SUNCT and SUNA are the other two types of TAC. Together, they are referred to as SUNHA [82]. The etiology and pathophysiology are not fully known. The association between these pathologies and posterior fossa lesions is well known, and recently the association between pituitary adenomas and these headaches has been discussed [83]. The pain generally occurs in the trigeminal area, more specifically in the V1 division and there is a high difficulty in differentiating between SUNHA and trigeminal neuralgia. These headaches have a sharp or burning character, last for a minimum of 5 seconds to a maximum of 10 minutes, and have a "sawtooth" development. A minimum of 20 pain attacks correlating with autonomic symptoms is required for clinical diagnosis, criteria defined by ICHD-3 [16,84]. The incidence is 0.1 per 10,000 population and the prevalence is 0.6 per 10,000 population [85].

The physiopathologic mechanism incriminated is represented by the activation of the trigeminal reflex and, similar to cluster headache, by triggering the hypothalamus [86]. Some recent studies have shown that trigeminal neurovascular conflict is important in the etiology of SUNCT and probably SUNA, with neuroimaging highlighting the similarity of changes in both pathologies, even assuming that the distinction between these two entities can be discarded [87,88]. High-resolution MRI imaging revealed neurovascular conflicts in more than 85% of patients with SUNCT or SUNA [87]. In addition, a recent study demonstrated ischemic changes in the left ventricular septal defect in approximately 15% of patients, leukoaraiosis in 5% of patients, and brainstem infarction in 5%. 88% of all patients had a vasculonervous conflict between the trigeminal nerve and certain vascular branches [85].

Therapeutically, the administration of many drugs used in other primary headaches has been tried, but with rather poor results. In this respect, SUNCT and SUNA differ from the other primary headaches. They respond mainly to the treatments used to treat neuropathic pain. Lamotrigine is effective in a large percentage of patients with the first pathology and less effective in the latter and is administrated at a dose of 100 to 300 mg daily. Topiramate isn't as effective as lamotrigine, and a smaller percentage of patients report symptomatology improvement. Carbamazepine is extensively studied and given in the treatment of these two pathologies, although with some poor results for the improvement of symptomatology in the SUNA group of patients. It is generally administrated in the standard dose of 200-1600 mg. Lidocaine is administered in an intravenous infusion of 1-4 mg/kg/hour to relieve severe headache attacks. Attempts may also be made to damage the trigeminal nerve or Gasser's ganglion by stereotactic surgery, radiofrequency stimulation, glycerol gangliolysis, or mechanical compression [89]. It is important to note that SUNCT and SUNA may also occur secondary to lesions at the level of the posterior fossa: damage to the cerebellum or brainstem by ischemic, tumoral, or vascular mechanisms. It is important to note that high-resolution MRI imaging studies can provide details about neurovascular compression, but these are not essential [2,21].

Hemicrania continua (HC)

Hemicrania continua is another primary headache that presents as a unilateral headache of moderate intensity with development over several months and belongs to the group of TACs according to ICHD-3 [2]. As the name implies, the pain is continuous and constant, but sometimes exacerbations associated with autonomic symptoms may occur. The response to indomethacin is pathognomonic [90]. It is estimated that the incidence of pathology is 1.0% and that continuous hemicrania accounts for approximately 1.5% of all primary headache cases [90]. Cases of continuous bilateral hemicrania were rarely presented [91]. According to ICHD-3, a clinical diagnosis requires a unilateral headache with pain duration of more than 3 months, ipsilateral autonomic symptoms, restlessness associated with the symptoms, and response to indomethacin treatment. Exacerbations may occur as a result of stress, alcohol consumption, or, in women, menstruation [90]. If HC is clinically suspected, cerebral MRI is recommended in all patients, and MRA or CT angiography of the head and neck should be indicated if an aneurysm or vascular pathology is suspected. Response to treatment with indomethacin is pathognomonic. Start with a dose of 25 mg three times daily, and if the patient does not respond to this treatment within 2-3 days, the dose is gradually increased up to a maximum of 300 mg per day [92].

Other primary headaches

Primary cough headache (PCH) represents a rare disorder in which bilateral cephalgia starts suddenly during coughing and may last up to two hours. According to ICHD3, the clinical diagnosis of primary-type headache is made by at least two episodes of pain that occur only after coughing or the Valsalva maneuver and last between one second and two hours, with no other associated intracranial pathology. However, up to 50% of patients hospitalized for this type of pain may have underlying lesions, such as Chiari malformation type 1, obstructive hydrocephalus, or tumors. Therefore, it is strongly recommended that imaging studies of the brain be performed, such as MRI or MRA [2,21,93]. Indomethacin is the treatment of choice for this type of headache [2].

Primary exercise headache (PEH) is a rare pathology similar to PCH, characterized by a bilateral pulsating headache that occurs only in the context of prolonged physical activity, lasting 45 minutes or less [2]. According to ICHD-3, when the patient first presents to the hospital with symptoms, it is mandatory to perform imaging studies to rule out "subarachnoid hemorrhage, arterial dissection, or vasoconstriction syndrome." Indomethacin is the treatment of choice for this pathology, in a dose of 25-150 mg before starting physical activity [94].

Primary headache associated with sexual activity is a diffuse bilateral headache that begins during sexual activity and lasts from 1 minute to 24 hours, accompanied by nausea or vomiting but without autonomic symptoms. These may present as progressive or sudden headaches, most often beginning at the moment of climax. Although it is generally not a serious medical problem, brain imaging is recommended to rule out other pathologies, such as subarachnoid hemorrhage or aneurysm [95]. It is difficult to quantify the epidemiology of this pathology because patients are reluctant to go to the doctor to be examined due to shame or ethical reasons. Some authors recommend prophylaxis with beta-blockers and symptomatic treatment with indomethacin [96,101].

Because of the rarity of these pathologies, there are no large, homogeneous studies quantifying the imagistic changes specific to each of these three pathologies, but rather small studies and case reports. For this reason, it is important to undergo a CT scan, especially in cases of sudden onset headache, to rule out secondary causes such as rupture of an aneurysm or subarachnoid hemorrhage, and subsequent vascular studies such as CT angiography or MRA are recommended in specific cases.

DISCUSSION

Despite the use of increasingly advanced imaging examination methods that have improved the understanding of the pathophysiology and mechanisms of development of primary headaches, the medical community still cannot fully understand and fully, optimally treat primary headaches. Structural MR imaging has demonstrated the presence of T2 and FLAIR hypersignal lesions that can be correlated with different pathologies that mimic the primary types of headache, although those appear especially with aura migraine. MR Perfusion imaging has shown several abnormalities in blood circulation and neuronal activity during cephalalgia exacerbations in every type of primary headache, demonstrating a lowering of pain threshold and, compared with the general population, deficient activation of many different areas in the brain responsible for interpreting pain, and in the case of migraineurs in particular, there is both a supernumerary activation of the areas as well as a more important or intense activation of them. Many authors have demonstrated that the autonomic nervous system takes part in the mechanism of headache development, due to age-related development and the decrease in headache amplitude in the case of noninvasive stimulation of the vagal endings for cluster headache prevention. These suspicions, especially in migraine, are not confirmed by imaging studies, either structural or functional. The use of imaging studies, regardless of their type, to diagnose migraine or tension-type headaches is not recommended because of the lack of specificity of the studies. Because these are debilitating diseases that affect both individual lives and society, sufferers search for answers and go from one physician to another in search of them. Repeated imaging studies in these cases represent a significant waste of resources, and each pseudonormal imaging result leads to even greater concern and anxiety about health status. The correlation of the new, recently discovered data with the clinical evolution of the patient can improve the selection and treatment of patients at risk for primary headache development, sometimes even from childhood. Today we know that primary headaches begin around the age of 5 years and the highest prevalence is found in the age group between 20 and 40 years, decreasing with age. The phenotypes and treatments of each pathology are different, even if they belong to the same class of pathologies. Currently, we can summarize that there are ischemic lesions, circulatory disturbances, vascular conflicts, 5th cranial nerve activation, and a lower pain threshold, all having their role in the development of these pathologies. Current studies include far too small and inhomogeneous groups of patients to be able to present convincing results regarding structural changes in the brain parenchyma or the various neuronal circuits.

CONCLUSIONS

In recent years, significant progress has been made in understanding the pathophysiologic mechanisms, both central and peripheral, of the primary cause of headaches, by using highly advanced technologies like structural high-resolution

MR, both of these imaging studies of cerebral structures allow the detection of cerebral parenchyma lesions with greater precision.

Pharmacologic interventions may help alleviate headaches, and recently several minimally invasive interventions have been tried, mainly targeting the physiopathologic mechanism that occurs via the cranial V nerve, obtaining promising results. However, there are still physiopathologic and imaging ambiguities related to these primary pathologies.

There is still an unmet need for studies in all fields, in large groups of homogeneous patients, to answer these questions.

Abstract: *The harmful effects of smoking cigarettes on human health are well documented; thus various smoking cessation methods have been assessed and new options are currently under development to provide a "better' alternative to the "worse" one, namely smoking. However, no ideal method of ending or replacing conventional smoking has been developed so far, and actually, none of them has been proven entirely effective or safe. The laxity, or rather the absence of regulations in the first decade of existence of electronic nicotine delivery systems (ENDS) allowed their use with prohibited substances instead of nicotine or other substances with detrimental effect, with the emergence of a severe syndrome - e-cigarette and vaping-associated lung injury (EVALI), whose treatment required even lung transplantation in young people without any prior underlying lung disease. This narrative review aims to provide a brief overview of concerns about medical issues associated with e-cigarette use, particularly cardiovascular and respiratory panels. We organized the data in several micro-sections varying from practical aspects of understanding ENDS to clinical issues. To combat tobacco addiction, electronic cigarettes are increasingly widely accepted. A global regulatory framework is required to prevent the emergence of an illicit e-cigarette business with detrimental impacts on health.*

Keywords: *e-cigarettes, EVALI, smoking, lung, respiratory, cardiovascular, pulmonary, electronic cigarette, ENDS*

INTRODUCTION

The harmful effects of smoking cigarettes on human health are well documented – from a simple addiction to a significant risk factor for lung cancer. Recent data places smoking as the leading risk factor for lung cancer, the most common type of cancer in the world, which is responsible for more deaths annually. The detrimental effects on cardiovascular, pulmonary, and reproductive systems are also considerable. Therefore, various smoking cessation methods have been assessed – behavioral, pharmacological, and combined methods and new options are currently under development to provide a "better' alternative to the "worse" one, namely smoking. However, no ideal method of ending or replacing conventional smoking has been developed so far, and actually, none of them has been proven entirely effective or safe [1-4].

Therefore, that's why there has been a continuous struggle to find smoking methods that do not involve burning nicotine, with heat-not-burn devices being the best, safest alternative, and an efficient smoking cessation tool. However, in the last decade, considerable evidence has been presented showing an induction of addiction in adolescents and smoking initiation in those who have never smoked both adolescents and adults. On the other hand, the laxity, or rather the absence of regulations in the first decade of existence of electronic nicotine delivery systems (ENDS) allowed their use with prohibited substances instead of nicotine or other substances with detrimental effects, with the emergence of a severe syndrome – e-cigarette and vaping-associated lung injury (EVALI), whose treatment required even lung transplantation in young people without any underlying lung disease. After the emergence of EVALI, which unfortunately has been overshadowed by the coronavirus disease-19 (COVID-19) pandemic, an increasing number of countries around the world have imposed regulations on the use of ENDS, which are now considered medical devices in some countries and are banned in others. Since it has been determined that the numerous flavors available to users have led to an increase in their use by adolescents, current legislation in most countries that have regulations limits the number and type of flavors available [5-8].

Aim

We aim to provide a brief overview of concern for medical issues associated with e-cigarette use.

METHODS

This is a narrative review of literature with no timeline restriction of research. We organized the data in several micro-sections varying from practical aspects of understanding ENDS to clinical issues.

ENDS – electronic nicotine delivery systems

ENDS include various devices, such as electronic cigarettes, e-hookahs, advanced personal vaporizers, and cig-a-likes. Currently, there are two main types of heat-not-burn products – tobacco heating devices and electronic cigarettes (four generations). From its first release in China in 2003 until today, the e-cigarette has undergone numerous improvements, with the current generation allowing a complex control of the device with significantly improved user safety. Electronic cigarettes are composed of an energy source (a rechargeable battery available from the second generation), a heating device - an atomizer, responsible for the generation of aerosols, a flow generator, a refillable (available from second generation) cartridge for e-liquid (water, propylene glycol, nicotine, flavors, and glycerol) and a mouthpiece. The third generation of e-cigarettes allows resistance and power adjustment while the fourth generation offers the possibility of temperature control (generally temperatures range from 40-65 Celsius), allowing for the modulation of the oropharyngeal experience [9-13].

It has been observed that by increasing the heating temperature, the aerosol generation rate also increases, and the aerosol particle size is modified as well (staying in the 100-600 nm range), with a potential impact on aerosol toxicity. Tobacco heating devices consist of a holder, an accumulator, and a nicotine heating unit (blade or induction heat technology) with aerosol generation. The differences between tobacco heat devices and e-cigarettes consist of user experience, the first one having a different operating time (6 minutes and a maximum of 14 puffs) and the temperature at which it operates (conventional smoking requires 200-600 Celsius). Nicotine is present in the tobacco that is used in the device. Also, not all e-cigarette devices use e-liquid with nicotine [14-19].

ENDS chemical compounds

E-liquid compounds include solvents (humectants or stabilizing agents), nicotine, cannabinoids, metals (in both the nicotine extract and the device constituents – nickel, manganese, copper, iron, arsenic, and lead), and flavors. The harmful effects of smoking are due to the inhalation of toxic products in cigarette smoke, generated by the combustion and pyrolysis of nicotine. Smoke from regular cigarettes contains more than 7000 different substances, including at least 70 carcinogens [20-24].

Unfiltered cigarette smoke is an aerosol with more than 400-500 gaseous components (nitrogen, oxygen, carbon monoxide and carbon dioxide, water, hydrogen, ammonia, argon, nitric oxide, hydrogen cyanide, hydrogen sulfide, methane, volatile alkenes, volatile alkenes, aromatic hydrocarbons - benzene, toluene, styrene, acids - formic acid, acetic acid, propionic acid, aldehyde - formaldehyde, acetaldehyde, acrolein, acetone, methanol, furan, pyridine, methylamine, etc.) as well as over 3500 other particulate constituents (nicotine, nornicotine, anatabine, anabazine, non-volatile hydrocarbons, carcinogenic polynuclear aromatic hydrocarbons, phenols, phthalates, polyphenols, acids – palmitic, stearic, oleic, linoleic, linolenic, lactic, indoles, quinolones, aromatic amines, nitrosamines and glycerol). In addition to these, various flavorings, pesticides, and metals are also present. Cigarette smoke contains 72 carcinogens and at least six compounds that harm reproduction [25-29].

Because they inhale both mainstream and sidestream smoke, passive smokers are more exposed to these dangerous substances than regular smokers. The amount of nicotine delivered by the e-cig is the result of several factors – smoking pattern (experienced versus inexperienced), aerosol characteristics (pH, particle size), pharmacokinetic and pharmacodynamics features, the site of absorption (oral or pulmonary), and of course the nicotine level in the e-liquid. The new generations of e-cigarettes deliver more aerosols and consequently higher amounts of nicotine, as demonstrated by their serum levels. The amount of nicotine in traditional cigarettes ranges between 10-15 mg nicotine/cigarette, of which 1-2 mg nicotine/cigarette is systemically absorbed, compared to 0-36 mg/mL liquid in electronic cigarettes [30-35].

E-liquid includes propylene glycol, vegetable glycerine, nicotine, and flavors. The e-cig structure includes absorbent materials in the atomizer (silicon, organic cotton, rayon fibers, stainless steel mesh, bamboo yar), as well as heating coils manufactured from different iron, chrome, aluminum, or nickel alloys. The usual heating temperature in early generation ENDS ranged from 45 to 60 degrees, but in new generations that allow the user to adjust the temperature, it can reach over 200 Celsius, resulting in the release of potentially harmful carbonyl products, such as acrolein in increased quantities at voltages above 3.3 V [36-39].

The most commonly encountered flavorings in e-cigarettes are diacetyl, acetoin (buttery flavor), benzaldehyde (almond/ cherry aroma), cinnamaldehyde (cinnamon aroma), cresol (leather aroma), eugenol (clove aroma) or isoamyl acetate (banana flavor). The products resulting from the conversion of liquid into aerosol can vary, the temperature obtained by heating in e-cigs not being uniform and depending on several factors – the volatilization rate, the effectiveness of aerosol absorption, product design, and battery voltage. Thus, by converting solvents, formaldehyde, acetaldehyde, acrolein, methyl glyoxal, and glyoxal are obtained, and from vitamin E, ketene, benzene, and alkene are generated [33-39].

Cardiovascular effects

As a result of nicotine absorption, there is a release of catecholamines with a secondary increase in heart rate, blood pressure, and heart contractility, concomitant with reduced coronary vascular flow and increased musculoskeletal flow. The decreased risk of cardiovascular disease has been demonstrated in both in vitro and in vivo studies. It has been shown a reduction in monocyte cell adhesion to endothelial cells, a reduction in platelet activation markers (thromboxane B2), oxidative stress markers (prostaglandin F2 alpha), and C-reactive protein and cholesterol [37-40].

The currently available studies have assessed both short-term and medium to long-term effects (years). Heart rate and blood pressure abnormalities have been shown to vary according to the smoking status of e-cigarette or former conventional tobacco smokers. Thus, in short-term use of e-cigarettes with or without nicotine, an increase in heart rate and blood pressure was observed, whereas in chronic smokers the data are not conclusive. In e-cig smokers, an increase in arterial pressure was found only for short-term users. In contrast to conventional cigarette smokers converted to e-cigarettes, the switch to ENDS reportedly promotes a reduction in cardiovascular risk and BP [41-45].

Respiratory system effects

Studies have consistently identified a significant association between using electronic cigarettes and respiratory disorders. At the pulmonary level nicotine acts by activating nicotinic receptors for acetylcholine resulting in bronchoconstriction by action on bronchial smooth muscle. Epigenetic changes resulting in reduced PPAR-gamma (mesenchymal peroxisome proliferator-activated receptor gamma) receptor expression results in an asthmatic phenotype. Lung nicotine levels are more than 200 times the systemic peak in both conventional smokers and vapers [46-48].

Propylene glycol and vegetable glycerine are used as humectants, but repeated inhalation is not associated with significant changes in lung function if the exposure is limited. On the other hand, the new generations of devices, which can reach temperatures above 300 Celsius, can generate toxic carbonyl volatile compounds – formaldehyde and acetaldehyde (at temperatures above 215 Celsius) and acrolein at temperatures above 270 Celsius, two compounds that are associated with exacerbation of bronchial asthma. Diacetyl (2,3 butanedione) a butter flavoring is known to induce irreversible acute bronchiolitis obliterans (long popcorn). Other flavorings such as cinnamaldehyde are known irritants for asthma and benzaldehyde is an irritant for the mucous membranes of the respiratory tract. Yet, benzaldehyde higher levels provided by newer generation ENDS were proven to suppress allergic inflammation in a murine model by decreasing the number of inflammatory cells in lung and nasal tissues [49-53].

Destructive effects on respiratory epithelial cells have been demonstrated in several in vitro studies, as well as on nasal epithelial cells [49-53]. In vivo research has shown reduced lung cancer risk in ENDS users [54-56]. Increased oxidative stress and mitochondrial dysfunction have also been demonstrated in in vivo studies [57-60].

Shortly before the COVID-19 pandemic, a new outbreak occurred in ENDS users- EVALI, with more than 2500 cases reported in the US over 5 months [61-72]. The predominant symptomatology was respiratory – dyspnea, cough, and chest pain, associated also digestive symptoms and fever. Most cases were caused by exposure to tetrahydrocannabinol while the remainder by exposure to vitamin E acetate which was used as a thickening agent. The latter is thought to alter the structure of the surfactant and by heating may generate keten, a toxic compound [73-77]. The introduction of regulations on ENDS status has led to a dramatic decrease in EVALI cases.

DISCUSSION

Apart from the mentioned inflammatory issues and the cardiovascular/respiratory associated entities related to the use of e-cigarettes, other medical consequences have been identified, yet, with various levels of statistical significance and some require further exploration to adequately assess their clinical impact.

For instance, while most studies have focused on pulmonary and cardiovascular effects, smoking is a well-known risk factor for oral cancer.

Current data shows a similar effect of e-cigarettes when compared to traditional tobacco smoking in terms of oxidative stress, wound healing arrest, promotion of a pro-inflammatory environment by increased pro-inflammatory cytokines, and incidence of periodontal disease, caries, and edentations.

However, the few available data on the carcinogenic effect of e-cigarette use have not led to any relevant practical conclusions, as they did not have a well-defined duration of exposure that enabled an objective risk assessment [78-84]. In addition to the direct effects on the user's health, environmental effects are described, which are attributed to the combination of compounds in mainstream and sidestream smoke.

Finally, as mentioned the most dramatic consequence in relationship with e-cigarette use is EVALI which particularly affects young individuals. While severe COVID-19 forms of infection might mimic an episode of EVALI, during pandemic years a growing number of hospitalizations for this syndrome had been registered.

The medical community increased the level of awareness concerning EVALI and recently various public health resources and scientific papers have been released to address this particular aspect [85-88].

CONCLUSIONS

Although ENDS are promoted as a safe alternative to smoking tobacco, it has been shown that adolescents who use them are more likely to start smoking tobacco again or start smoking it for the first time. Smoking is a significant global public health issue. The methods for quitting smoking have changed over time, but none have achieved perfect success. To combat tobacco addiction, electronic cigarettes are increasingly widely accepted. A global regulatory framework is required to prevent the emergence of an illicit e-cigarette business with detrimental impacts on health.

Abstract: *Bariatric surgery represents one of the most efficient treatments addressing obesity and its associated complications with an increasing trend. Even if the medical benefits for patients are huge, due to weight loss and despite technical improvements in bariatric procedures, it is still associated with diverse types of complications. Most of the complications appear due to nutrient deficiency, as absorption is compromised after surgical anatomy modification. Neurological complications after bariatric surgery are very diverse with an occurrence within days to years after surgery, most frequently in patients with gastrointestinal or surgical complications. Any segment of the nervous system can be affected with distinct types of manifestations ranging from peripheral axonal neuropathy, nerve palsy secondary to compartment syndrome, encephalopathy, and myelopathy, to psychiatric and demyelinating central nervous system diseases. Identifying patients at risk and systematic screening for nutrient deficiency with proper supplementation is essential for preventing neurological complications and lifelong sequelae. In this paper, we present the spectrum of neurological complications reported after bariatric surgery.*

Keywords: *bariatric surgery; nutrient deficiency; neurological complications*

INTRODUCTION

Bariatric surgery still represents one of the most efficient treatments addressing obesity and because the incidence of severe obesity is rising worldwide, more and more bariatric procedures are done annually in specialized medical centers. Even if the medical benefits for the patients are huge due to weight loss and despite the technical improvements for bariatric procedures, it is still associated with different types of complications.

Most of the complications are due to the modified anatomy which leads to impaired absorption of the nutrient, besides the inflammatory state and mechanical stress induced by surgical procedure. The most common complications are gastrointestinal and surgical complications and include but are not limited to reflux disease, vomiting, dumping syndrome, leaks with high mortality getting up to 15%, stenosis, twists and kinks causing dysphagia, bleeding, enteric perforations, internal hernias, bowel obstruction, ulcerations, and gallstones disease. Other complications seen following bariatric surgery are weight regain, pulmonary thromboembolism, metabolic and hematological disorders, such as anemia, leucopenia, and neuropsychiatric complications. [1]

MATERIALS AND METHODS

The purpose of our paper was to review the existing literature data regarding the neurological complications that occurred after bariatric surgery and the presence of nutrient impairment.

We performed a scoping review of the published literature, and we included original studies, reviews, and a series of cases by searching the Medline, PubMed, and Google Scholar databases. We included articles written in the English language.

We searched for the terms: “bariatric surgery”, “neurological complications and bariatric surgery”, “nutrient deficit and bariatric surgery”, “vitamin deficit and bariatric surgery”, “gastric sleeve”, “gastric banding”, “gastric bypass”, “vertical gastroplasty”, “obesity surgical treatment”.

We excluded papers with respect to bariatric surgery-related complications and pre-operative nutritional deficiencies.

NEUROLOGICAL COMPLICATIONS

Neurological complications after bariatric surgery were reported in 3-16% of cases and usually affected more than one component of the nervous system [2,3].

Neurological disorders are various and affect mainly the peripheral nervous system and less common central nervous system, but both are associated with a poorer quality of life and substantial morbidity. Neurological complications of these patients might occur days to years after surgery and include peripheral neuropathy, compartment syndrome, plexopathy, mononeuropathy, encephalopathy, myelopathy, ataxia, myopathy, myotonia, behavioral and psychiatric disorders [2,3,4].

The physiopathology of neurological impairment comprises nutritional deficiency, rapid weight loss, and compartment syndrome. The vitamin B12 shortage, thiamine deficit, and decreased levels of copper are the most commonly deficient nutrients responsible for neurological conditions development after bariatric surgery. Deficiency of riboflavin, pyridoxine, folate, vitamin D, E, phosphorus, calcium, selenium, zinc, and iodine can also contribute to neurologic dysfunction [3,5].

Impact Of Vitamin and Micronutrient Deficiency After Bariatric Surgery and Neurological Complications

Nutritional impairment after bariatric surgery is quite common and manifests a large spectrum of vitamin and micro-nutrient deficiencies affecting both, the water-soluble vitamins (thiamine, riboflavin, pyridoxine, folate, cyanocobalamin, vitamin C), and the liposoluble ones (A, D, E, K), alongside the fat malabsorption, loss of proteins, and minerals deficiencies (iron, zinc, copper, selenium). All these associate different clinical manifestations within a variable time frame of appearance and usually are overlooked by clinicians. Some bariatric procedures, such as Roux-en-Y gastric bypass and post-biliopancreatic diversion/duodenal switch put the patient at higher risk of developing multiple nutritional deficiencies since the absorptive surface is reduced or bypassed [5,6].

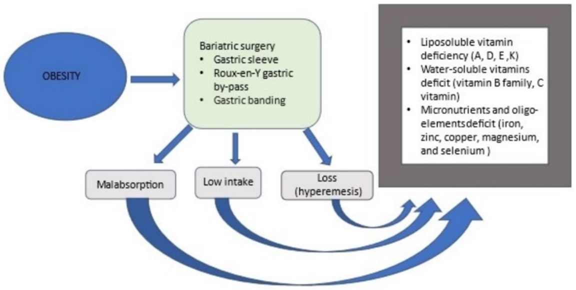
The most common deficiencies reported after bariatric surgery are iron deficiency (which was found in more than 30% of patients) [5], cobalamin and folate deficiency in up to 35%, respectively 39% after five years [6], and thiamine deficiency in 49% of patients [7].

Reports from a French cohort study showed a high rate of overall vitamin B deficiency (74%), with thiamine deficit in more than 47% of the cases [8]. A significant number of patients, up to 30%, already had micronutrient deficiency before bariatric surgery which increased the risk of new complications [9]. Hypovitaminosis D after bariatric surgery was reported in 25-70% of the patients, with calcium deficiency in 10%, but it should be considered that obesity is associated with suboptimal 25-hydroxy-vitamin D and 30% of obese patients could have vitamin D deficiency [10,11]. Vitamin E deficiency was reported up to 65.7% in a recent systematic review, and vitamin A in 5-69% in 2-4 years following surgery. Clinical manifestations of vitamin E deficiency are usually seen after Roux-en-Y gastric bypass, being mainly neurological (ataxia, peripheral neuropathy), but also hemolytic anemia, impaired immune response, ophthalmological disorders, infertility, and nystagmus can occur [12]. Although rarely clinically manifested, deficiency of vitamin C and vitamin K was reported in almost half of the patients [6,12].

Low zinc level after bariatric surgery was associated with high inflammatory status. There are reports of necrolytic migratory erythema with severe bacteremia and optic neuropathy due to zinc depletion [13,14]. The zinc repletion therapy should be done cautiously because it can induce copper deficiency. The copper deficiency occurs mostly after gastric bypass as its absorption occurs in the stomach and duodenum. Many cases of copper deficiency had been reported up till 9 years after bariatric surgery with capricious clinical expression, the majority mimicking vitamin B12 deficiency, consisting of myelopathy, ataxia, peripheral neuropathy, optic neuropathy, blindness, muscle weakness, anemia, and neutropenia [15,16, 17,18].

The diagnosis of copper deficiency usually requires the measurement of serum levels associated with the ceruloplasmin level under 20 mg/dl and C reactive protein because ceruloplasmin is an acute phase protein and levels could be misinterpreted in inflammatory states. MRI study with T2 hyperintensity in the posterior dorsal column of the spinal cord can suggest the diagnosis [19,20].

Most of the neurological complications are often seen in patients with surgical complications, longer hospitalization time, or those with gastrointestinal symptoms, especially protracted vomiting. Moreover, these patients underwent a surgical reintervention in 8-32% of the cases [8,21].



OBESITY
Bariatric surgery
• Gastric sleeve
• Roux-en-Y gastric by-pass
• Gastric banding
Malabsorption
Low intake
Loss (hyperemesis)
• Liposoluble vitamin deficiency (A, D, E ,K)
• Water-soluble vitamins deficit (vitamin B family, C vitamin)
• Micronutrients and oligo-elementsdeficit (iron, zinc, copper, magnesium, and selenium)

Figure 1: Pathophysiology mechanisms of neurological complications after bariatric surgery and types of nutrient deficiencies

Peripheral nervous system complications

Neuropathy is the most frequent neurological complication described after bariatric surgery and has been reported in 16% of patients after this type of procedure [22]. Its occurrence is induced by vitamin deficiency, especially thiamine, and cobalamin, which are involved in myelin synthesis, but also riboflavin, pyridoxine, and copper deficiency [21].

Another mechanism of occurrence is attributed to entrapment and mechanical compression. Rapid weight loss with subcutaneous protective fat tissue disappearance and inaccurate leg postures can cause compression neuropathy, frequently unilateral. Involvement is usually sensory predominant with late motor progression, chronic and symmetrical, mostly affecting distal limbs, but also small fiber neuropathies and bilateral neuropathies were several times described, contrary to plexopathy which was rarely seen [23,24].

The median nerve compression, the peroneal nerve palsy, and the ulnar nerve palsy were the commonest nerves affected after bariatric surgery. Peroneal nerve palsy is usually unilateral, but cases with bilateral affection were described.

Rapid weight loss with a mean of 45-50 kg reduction in several months is the main risk factor identified for peroneal nerve injury as the nerve's superficial anatomic localization makes it susceptible to impingement [24]. One case of meralgia paresthetica after bariatric surgery was described in an Asiatic report [25]. Rare cases of dry beriberi disease characterized initially by nausea, vomiting, constipation, severe weakness and then progressing to feet tingling and burning were described in the literature with late diagnosis, which was only suggested after performing electromyography [26].

A few cases of acute axonal polyneuropathy resembling Guillain Barre syndrome, rapidly progressive were described in the medical literature after bariatric surgery with good response to vitamin B1 and B12 high dose replacement [27]. There are also recently reported cases of mixed polyneuropathy after bariatric surgery both axonal and demyelinating after five to 24 months post-surgery and some case reports of Guillain Barre syndrome, raising the suspicion that bariatric surgery could induce immunological changes which predispose to autoimmunity [14,28]. Cases of plexopathies affecting the lumbar plexus were reported, manifesting with unilateral severe pain with sensory loss in the hip and thigh region, muscle wasting, patellar reflex loss, and extensive denervation on electromyography study [25].

Several other risk factors for predicting neuropathy development, despite rapid weight loss, were previously reported, such as low albumin and transferrin levels, gastrointestinal complications, surgical complications with long hospitalization, jejunoileal bypass, and lack of nutritional assessment after bariatric surgery [22]. Symptoms of neuropathies include pain, paresthesia, burning feet in small fiber neuropathy, usually progressive weakness, and rarely acute, foot drop, slapping gait, loss of reflection, and objective sensory loss. The diagnosis is confirmed by electromyography studies indicating distal axonal neuropathies. Biopsies of the affected nerves show axonal degeneration and peri-vascular inflammation [24,29].

Treatment includes a high dose of vitamin B12 dose of 1000 ug intramuscular once daily for a week and then weekly, vitamin B1 500 mg daily, intravenous for three days, and afterward 100 mg oral route and acid folic supplementation 5 mg per day, with good response and resolution of symptoms. Vitamin supplementation should be done for long periods and started as soon as possible when diagnosing neuropathy in post-bariatric surgery patients without waiting for confirmation of vitamin deficiency tests since vitamin levels can be normal. Nerve decompression was cited as the most efficient therapy for peroneal nerve entrapment after bariatric surgery [23]. Intravenous immunoglobulin is the treatment of choice for Guillain Barre syndrome, with a good response. Physical therapy can be used as a complementary treatment to vitamin replacement when treating neuropathy [24,29].

Functional impairment is usually mild, but it can be debilitating when the neuropathy becomes chronic or when the patient experiences weakness and foot drop. Also, small fiber neuropathy can evolve into distal neuropathic chronic pain syndrome in all extremities, deteriorating life quality [24,29].

Central nervous system complications (CNC)

The most reported CNS complications after bariatric surgery are encephalopathy, myelopathy, neuropsychiatric disorders, and optic neuropathy [30].

Encephalopathy

The most common type of encephalopathy seen after bariatric surgery is Wernicke encephalopathy secondary to thiamin deficiency, but also different types of encephalopathy are being described, such as hyperammonemia encephalopathy due to high plasmatic levels of glutamine and ammonia, zinc deficiency and urea cycle disorders. Episodic encephalopathy associated with D lactic acidosis is another type of encephalopathy encountered after bariatric surgery, usually precipitated by high carbohydrate intake, and hardly diagnosed by clinicians [31,32].

Clinical manifestation of Wernicke encephalopathy consists of acute confusion, ataxia, nystagmus, sometimes associated with cranial nerve palsies (third and sixth), seizures, dysarthria, myoclonus, asterixis, papilledema, vestibular symptoms, blurred vision, and polyneuropathy. Almost 80% of patients surviving encephalopathy develop Korsakov syndrome defined by amnesia (retrograde and anterograde), confabulation, and loss of insight, being more common in alcohol consumers. Most cases of Wernicke encephalopathy occur between 14 days to 1-2 years, mostly in women, and are usually precipitated by several factors. Vomit-ing is the most common gastrointestinal symptom precipitating Wernicke encephalopathy, usually preceding thiamine (Gloy VL) deficiency manifestations [8,12,33]. Other factors include rapid weight loss, food avoidance, poor appetite, and lack of vitamin supplementation, as thiamine reserves are depleted in less than 3 weeks without supplementation. In the absence of rapid diagnosis and appropriate treatment, the disease is fatal. Diagnosis of Wernicke encephalopathy is usually clinical, supported by laboratory and IRM studies. Tissue thiamine levels are accurately determined by red blood assays of specific enzymes (erythrocyte transketolase activity coefficient since blood and urine levels are not reliable [34].

IRM changes in Wernicke encephalopathy include symmetrical increased signal on T2/FLAIR phase in dorsomedial thalami, mamillary bodies, tectum plate, periaqueductal area, and around the third ventricle. Treatment of Wernicke encephalopathy consists of intravenous/intramuscular of thiamine 100 mg for 3-5 days minimum, followed by 30 mg twice orally for several months and correction of hypo-magnesemia since magnesium is a cofactor in thiamine-dependent metabolism. Prevention is mandatory and patients at risk should get thiamine supplementation of 100 mg intramuscularly followed by 50 orally once daily. Recovery in Wernicke encephalopathy induced by bariatric surgery after optimum thiamine supplementation is seen in more than half of the cases, the others remaining with cognitive deficiencies, gait disturbances, nystagmus, psychosis, and rarely death [15,30,33].

Hyperammonemia encephalopathy represents a particular type of encephalopathy recognized in the past years in patients who have undergone Roux-en-Y gastric bypass with a high mortality rate, characterized by a high level of ammonia in the absence of liver disease [31]. In a review from Andrew Z. Fenves et all in 2015 a mortality rate of 50% was reported in these patients with a predominance of women as the conditions were most often seen in this category of patients [35].

Laboratory findings include mild to moderate increased levels of ammonia, high levels of plasma glutamine, low albumin and zinc levels, essential amino acids deficiency, and reactive hypoglycemia [36].

The precise mechanism of onset is not yet understood, but several factors were until now described in the hyperammonemia state after bariatric surgery. Most of the lethal cases of hyperammonemia encephalopathy showed genetic predisposition caused by urea cycle abnormalities with a partial ornithine transcarbamylase deficiency or a mild carbamyl phosphate synthetase (CPS) deficiency [32].

One of the predisposing factors for hyperammonemia is the presence of huge nitrogenous residues in the liver. Intake reduction triggers a high catabolic state with protein breakdown. Ammonia level is also increased by altered gut microbiota that produces more urea lithic strains because of small bowel pouches created by bariatric surgery [31,36]. Case reports from patients with this neurological complication after bariatric surgery reported lower citrulline levels in the intestine affecting ureagenic capacity. Moreover, other predisposing conditions as the presence of a splenorenal shunt should be suspected and ruled out in patients developing hyperammonemia [32,35].

Therapeutic options include protein intake reduction, zinc and amino acid repletion, parenteral glucose, lipid supplementation, and oral lactulose. In refractory cases, hemodialysis and setting back of surgical procedures could be an option [37].

D-lactic acidosis encephalopathy is a rare condition reported mostly in short bowel syndrome, but also described years after bariatric surgery, especially after jejunum-ileostomy, and should be taken into consideration in a patient with anatomic changes of the digestive tract who develops confusion syndrome [38]. Confusion episode is associated with behavioral changes, dysarthria, ataxia, lethargy, and weakness, and is usually triggered by high carbohydrate intake. D lactate serum elevation is a result of carbohydrate fermentation in the small bowel or colon and is hardly diagnosed as serum and urine measurement of D lactate is not commonly done, L lactate being the only form that is most frequently checked when assessing lactic acidosis. A level over 3 mmol/l is diagnostic for this pathology and is often associated with a high serum anion gap [38]. Treatment involves metabolic acidosis correction with intravenous bicarbonate, fasting reducing carbohydrate levels, and intravenous amino acids, but also modulating intestinal microbiota with antibiotics which improve neurological symptomatology [39].

Myelopathy is usually seen years after bariatric surgery being one of the most disabling complications. It commonly affects posterior columns with the dorsal ganglia root and can be also associated with neuropathy (myeloneuropathy) or optic neuropathy. Manifestations consist of vibration and proprioception loss, gait ataxia, hyperreflexia, and Babinsky sign, sometimes accompanied by sphincter dysfunction and limb weakness [40].

When neuropathy occurs sensory changes in glove and stocking patterns are also seen in these patients after bariatric surgery. This complication is caused primarily by cobalamin deficiency but is also attributed to other deficient nutrients such as copper, vitamin E, and pyridoxine. Correction of these micronutrients initially intravenously and then long-term orally or intramuscularly for vitamin B12 improves neurologic symptomatology but without full recovery in some patients. For optimum management copper levels should be regularly checked and supplemented as quickly as needed initially intravenous and then oral administration [41].

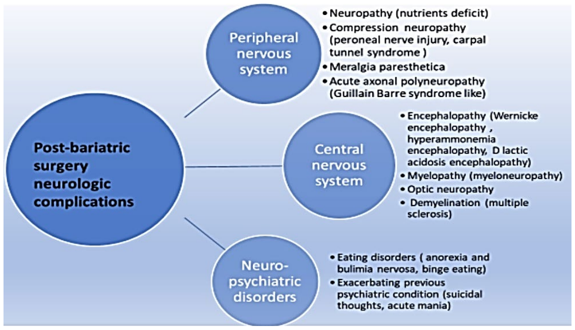
Optic neuropathy affecting one or both side nerves is associated with bariatric procedures because of nutritional deficiencies in vitamin B12 and vitamin A, copper, and rarely zinc, causing malfunction of nerve fibers. The onset can vary during a large period and can be acute or progressive causing blindness. As optic neuropathy pathogenesis is linked to demyelination, permanent blindness may not be overcome [22,42].

Central nervous system demyelination presenting as multiple sclerosis which fulfilled the McDonald criteria for diagnosis was reported in a series of cases after various types of bariatric surgery with relapsing-remitting forms [4,43,44], without understanding the mechanism of appearance or the exact relationship between the events, but it might be attributed to rapid and substantial weight loss. Other previous case reports also described multiple sclerosis onset and myasthenia gravis after rapid weight loss induced by bariatric surgery or highly restrictive diets [45]. Two cases of monophasic central nervous system demyelination were also reported by Falah et al in a series of patients with neurological complications after bariatric surgery, and in a Brazilian study [44].

NEUROPSYCHIATRIC DISORDERS

Neuropsychiatric disorders are seen after bariatric surgery, usually consisting of eating disorders (anorexia and bulimia nervosa, binge eating, avoidance eating (post-surgical avoidance eating disorder), reports of acute mania [46], and higher risk of suicide. These disorders frequently appear in preexisting psychiatric conditions, making psychiatric evaluation before surgery mandatory to find patients at risk who need to be followed. Several cases of cognitive complaints were described following bariatric surgery in Roux-en-Y Gastric Bypass induced by focal brain atrophy in the bilateral posterior thalamus [47] but need to be further studied.

Other conditions described after bariatric surgery with higher incidence are stroke, seizures [48,49], spontaneous intracerebral hypotension linked to vitamin A, and D deficiency, and spontaneous leakage of cerebrospinal fluid, but the exact relationship needs to be established in future studies [30].



Post-bariatric surgery neurologic complications
Peripheral nervous system
• Neuropathy (nutrients deficit)
• Compression neuropathy (peroneal nerve injury, carpal tunnel syndrome)
• Meralgia paresthetica
• Acute axonal polyneuropathy (Guillain Barre syndrome like)
Central nervous system
• Encephalopathy (Wernicke encephalopathy , hyperammonemia encephalopathy, D lactic acidosis encephalopathy)
• Myelopathy (myeloneuropathy)
• Optic neuropathy
• Demyelination (multiple sclerosis)
Neuro-psychiatric disorders
• Eating disorders (anorexia and bulimia nervosa, binge eating)
• Exacerbating previous psychiatric condition (suicidal thoughts, acute mania)

Figure 2: The spectrum of neurological complications described after bariatric surgery. From peripheral to central nervous complications, to neuropsychiatric disorders.

CONCLUSIONS

Complications after bariatric surgery have a broad spectrum of manifestations involving both the peripheral and central nervous system and should be suspected and diagnosed as soon as possible to prevent long-term sequelae. The risk of developing central nervous system demyelination or stroke events after bariatric surgery should be further evaluated in future studies. Patients with rapid weight loss and those who develop gastrointestinal symptoms and surgical complications are considered at high risk for developing neurological complications, which is why nutritional deficiency assessment and supplementation should be done as early as possible.

Abstract: *This review explores the trajectory of photoplethysmography (PPG) technology from its inception in 1934 to its integration into smart devices in 2013. While PPG has proven effective in estimating left ventricular ejection time (LVET) and distinguishing between hypertensive and normotensive patients, challenges persist. The need for a robust mathematical model to explain physiological behaviors, address calibration protocols, and handle waveform variability is emphasized. Despite limitations, PPG is on the cusp of achieving clinical-grade confidence, particularly in estimating blood pressure and tracking vasomotor states. Integration into wearable devices is a prominent trend, with major companies exploring applications for improved health monitoring. Open-source databases and the availability of physiological data aim to enhance understanding, paving the way for universally accepted protocols. As PPG advances, it holds promise for personalized healthcare, revolutionizing treatment evaluations and preventive measures. However, potential disagreements over protocols may impede progress. Nevertheless, the technology's potential to remotely monitor cardiovascular markers could reduce physicians' workload for routine tasks. PPG stands as a beacon for the future of noninvasive cardiovascular assessment.*

Keywords: *photoplethysmography roadmap; cardiovascular assessment; cardiovascular disorders; left ventricular ejection time; blood pressure estimation*

INTRODUCTION

Cardiovascular diseases are, according to WHO, the most common cause of death globally. There are made continuous efforts to reduce the incidence, morbidity, and mortality of these conditions. All over the world, the physicians involved in preventing, detecting, and treating cardiovascular diseases are insufficient and subjected to an overwhelming workload: theoretically, after a certain age, virtually all individuals have a certain risk of developing cardiovascular conditions and these patients, after diagnosis, need periodical evaluation for monitoring, assessment of treatment efficacy and, also, management of complications. Therefore, in the context of nowadays technology capabilities, it has raised the question if there could be developed some methods to monitor these patients over a distance, using suitable medical technologies to non-invasively measure some biomarkers.

At present, it is available to remotely measure, using various wearable devices, pulse, SpO_2 and to record an ECG. However, in detecting or monitoring the risk of adverse events, it would be useful to be able to remotely monitor arterial blood pressure, hypertension being the most prevalent cardiovascular risk factor, or, more advanced, to monitor various parameters of heart performance.

Photoplethysmography (PPG) technology has already demonstrated promising efficiency in distinguishing between normotensive and hypertensive patients or in estimating left ventricular ejection time. In our opinion, with more research in this field and with better mathematical models that can explain all physiological behaviors, PPG could help healthcare professionals offer personalized care regarding the prevention, treatment, and follow-up of cardiovascular diseases.

PHOTOPLETHYSMOGRAPHY APPLICATIONS

Short History

The founding concept of the PPG technique is older than a century when German physicist M.R. Bonnsman invented a photocell device in 1934 intended for peripheral blood volume evaluation [1]. This novel method was taken over by Alrick Hertzman [2,3] for further investigations in the physiological domain. Based on numerous experimental investigations, but limited by the technology capabilities at that time, he proposed blood volume variation as the origin of the PPG signal. No new progress in this technique has been made in the next years since the associated sensor was more of a tool in circulation research.

A valuable clinical application emerged in the form of blood oxygen saturation ratio (SpO_2) [4], pioneered by Takuo Aoyagi in the 1970s [5]. The device, now known as a pulse oximeter, was introduced into U.S. clinical monitoring a few years later, confirming its utility. Following this significant advancement, there was no immediate surge in research within the PPG technology domain; instead, efforts were concentrated on enhancing the accuracy of SpO_2 measurements. The pulse oximeter device became commercially accessible in the 2000s, owing to technological advancements and its availability in the open market [6].

Technology nowadays

The subsequent period that drew attention to PPG was marked by the integration of this technology into the first smartwatches in 2013 [7]. This significant development raised awareness among both academic and industry researchers regarding the potential for cardiovascular monitoring through wearable devices. While the well-established SpO_2 measurement and heart rate determination are valuable for assessing heart performance during resting periods or intense activity [8,9], they do not constitute a comprehensive tool for physicians to remotely monitor a patient in terms of cardiovascular disease (CVD) prevention or tracking.

Therefore, intense research has commenced in the PPG domain over the last decade, exploring various capabilities as depicted in Figure 1. One sought-after application is noninvasive arterial blood pressure (ABP) monitoring, considered a crucial hemodynamic marker in the evaluation of cardiovascular diseases (CVD) [10,11]. By incorporating this targeted assessment into smart devices such as watches, bracelets, and rings, personalized healthcare becomes accessible for end-users. The confidence in this feature has prompted major companies like Samsung [12] to integrate it into their devices. Start-ups such as Valencell [13] and Aktiia [14] assert their ability to provide this measurement using Machine Learning (ML) techniques. Additionally, numerous individual research entities report significant progress in this direction, leveraging artificial intelligence (AI) networks [15].

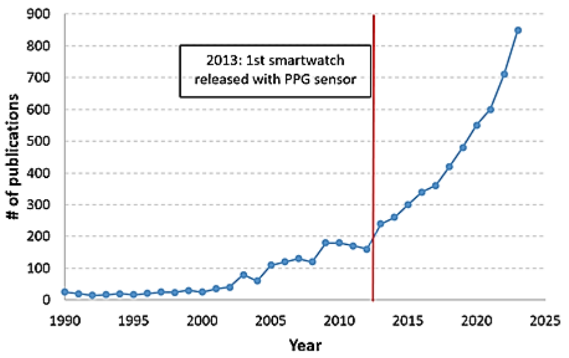

Figure 1: A timeline of PPG-related publications every year from 1990 to 2023. Data obtained from Google Academic, last accessed on 15th December 2023

The key factors contributing to the popularity of PPG encompass the mitigation of motion artifacts, the precision of SpO_2 readings and heart rate measurements, initiatives for extracting arterial compliance, and the estimation of blood pressure. Furthermore, a novel approach, remote photoplethysmography (rPPG) [16], has emerged in recent years, focusing on extracting hemodynamic information through facial recognition. The advancement of information technology, notably the internet and easy access to information, has played a significant role in augmenting the popularity of PPG.

However, as depicted in Figure 1, the upward trend in the number of publications does not align with the maturity of the technology. Regrettably, numerous topics are repetitive, merely contributing to the validation of specific assessments rather than yielding outstanding discoveries or breakthrough research. As will be presented in the next section, a strategy focused solely on PPG signal interpretation is not sustainable. Reflective sensors are commonly employed for wearable applications, as illustrated in Figure 2, in contrast to the transmissive ones more prevalent in clinical settings.

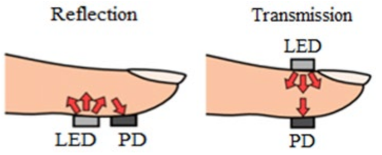

Figure 2: Two types of PPG modes: reflective and transmissive. In wearable devices, the first mode is prevalent, while in clinical settings the second one is present.

Eligible models must be developed to comprehensively explain all observed physiological behavior, and the correlation or causation with arterial blood pressure needs to be elucidated. Without such a focused direction, the repetition of topics will persist without yielding new and significant discoveries.

PPG as a standalone biomarker

As a standalone biomarker, information extracted from PPG waveform contour analysis becomes crucial. Following this approach, significant features such as the tidal wave (TDW) [17] and the dicrotic wave (DCW) [18] can be associated with the vasomotor state. The latter waveform component proves to have a strong correlation in estimating vasomotor tone, as observed in Figure 3, where the dicrotic notch sharpens proportionately with the level of vasodilation [19]. When combined with other waveform markers, such as the ratio between systolic upstroke and downstroke, and aided by Machine Learning (ML) models, the hypertensive state can be reliably detected [20].

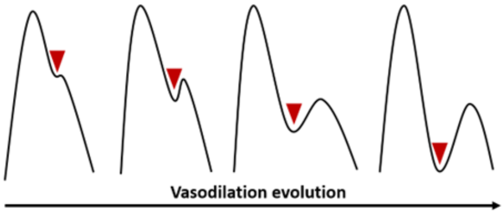

Figure 3: Evolution of PPG waveform during vasodilation progress, by highlighting incisura or DCW feature. Reconstructed after the findings on [19]

Another application involves the myocardial performance index (MPI or TEI) [21], as the PPG waveform encompasses information about isovolumetric contraction time (IVCT) [22], isovolumetric relaxation time (IVRT), and left ventricular ejection time (LVET) [23]. Despite the potential for overestimation and underestimation of measurements due to the hemodynamic state, these values closely align with the golden standard method of Doppler echography.

PPG in sensor fusion

One popular technology in this category is represented by the pulse pressure transit time (PTT) method [24], developed for arterial compliance and blood pressure assessment. The current literature protocol [25] guides the measurement of this marker from the electrocardiogram (ECG) R peak to the PPG systolic point, as depicted in Figure 4.

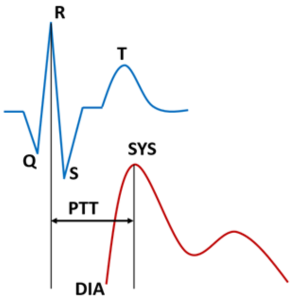

Figure 4: PTT protocol based on guidelines [25]

Based on the physical equation developed by Moens–Korteweg [26], which describes the traveling behavior of mechanical pulse pressure, blood pressure estimation can be extracted. Thus, a stiffer system will promote rapid traveling of the pulse wave, resulting in a shorter PPT time. Conversely, an elastic system, due to its ability to absorb mechanical energy, will slow down the traveling mode, leading to a longer measured time.

Another application that combines PPG capabilities involves fusion with a medical cuff. During cuff inflation, PPG acts as a monitor of blood supply at the targeted site. After a certain point, the externally induced pressure will trigger blood vessel occlusion, which is reflected by a missing PPG waveform. This measurement approach was embedded in the Omron smartwatch [27] to enhance the accuracy of blood pressure assessment.

A recent application involves remote photoplethysmography [16], which targets face recognition in combination with pulsatile detection of facial skin. By selecting two separate regions of interest (ROI), such as the chin and forehead, equivalent approaches to the PPT technique are employed to compute and estimate blood pressure, as depicted in Figure 5.

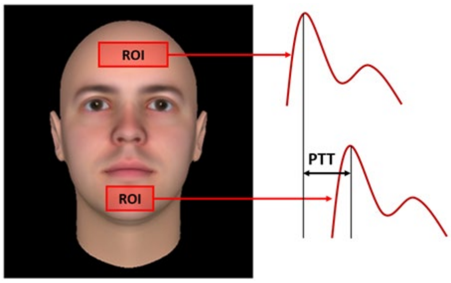

Figure 5: Principle of rPPG. Two locations of skin pulsation generate PPG waveform but with a time delay in between. This delay is exploited by a similar to the PPT method to extract blood pressure estimation

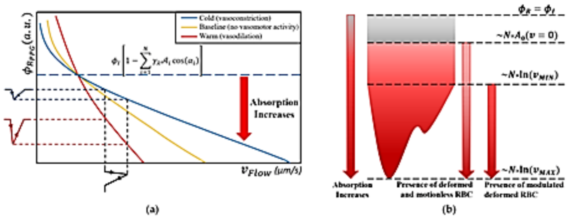
PHOTOPLETHYSMOGRAPHY LIMITATIONS

Physiological model

Despite the important and useful applications of the PPG technique, either standalone or in conjunction with other methods, the technology has demonstrated some limitations.

The first significant limitation pertains to the proper understanding of PPG origin, particularly in relation to pulse formation. While Alrick Hertzman proposed blood volume variation as a working model in the 1930s, recent investigations have revealed some drawbacks. One common limitation arises during reduced SpO_2 readings [28], which actually represent the ratio between oxygenated and deoxygenated blood volume. Additionally, the hand position concerning the heart level [29] modulates the PPG waveform amplitude according to specific rules, contrary to the initially proposed volume variation model. Therefore, significant progress in the hemodynamic domain cannot be achieved without a suitable PPG model that can explain and predict different physiological states. At this juncture, two mathematical models are required: one to elucidate the optical nature of the recorded signal and another to describe the mechanical nature that provides a specific waveform morphology. Training Machine Learning (ML) or Artificial Intelligence (AI) systems with a large set of hemodynamic data will not unveil the true relationship between these two physical quantities. Instead, it serves as an interim step to understand which waveform components are predominant in blood pressure assessment.

A recently developed model proposes the red blood cell deformation effect as the origin of PPG formation [30]. The mere presence of erythrocytes in the measurement area modulates the direct component or baseline of the recorded waveform. Interestingly, as cells move under a defined velocity field, they deform in the capillary regime. Thus, targeting red blood cells with light results in the absorption of radiant flux proportional to the deformation level. Given that many publications attempt to correlate arterial blood pressure (ABP) waveform with PPG, it is observable that the physiological stimuli contributing to PPG formation are the blood flow velocity at the capillary level, ranging from 50 µm/s to 2000 µm/s [31]. As a result, as depicted in Figure 6, the PPG waveform is exclusively modulated by the velocity values through the capillary network, reflected in the final waveform by red blood cell deformation.



Cold (vasoconstriction)
Baseline (no vasomotor activity)
Warm (vasodilation)
$\phi_{R_{PPG}}(a.u.)$
$\phi_I\left[1-\sum_{i=1}^{N}\gamma_{Ri}A_i\cos(\alpha_i)\right]$
Absorption Increases
v_{Flow} (µm/s)
(a)
$\phi_R = \phi_I$
$\sim N\cdot A_0(v=0)$
$\sim N\cdot \ln(v_{MIN})$
$\sim N\cdot \ln(v_{MAX})$
Absorption Increases
Presence of deformed and motionless RBC
Presence of modulated deformed RBC
(b)

Figure 6: RBCM MODEL. Reused from [30]

It is important to note that both the mechanical blood pressure pulse and red blood cell deformation—precursors for PPG—are driven by blood flow velocity. Therefore, this physical quantity serves as the same input stimulus, the causal factor, for both associated waveforms. In this context, a correlation rather than direct causation exists between arterial blood pressure (ABP) and PPG information. From this standpoint, estimations of hemodynamic markers can be extracted with the aid of wearable technologies. However, due to the logarithmic nature of PPG origin, as depicted in Figure 6, the hemodynamic information will undergo modifications that could lead to wrongly interpreted results.

Finally, without a proper optical model, the improvement of pulse oximeter sensors becomes challenging. The most critical design considerations are related to mechanical features, such as the frequency of the LED used, initial light flux power, and the arrangement of the photodiode. In terms of signal processing, important design inputs include signal amplification, sampling frequency, and filtering stages.

Measurement protocols

All the aforementioned PPG measurement capabilities require a universally agreed-upon protocol to ensure that different devices provide consistent results for the same user or patient. This requirement is crucial for accurate measurements to be eligible for clinical applications. Moreover, regardless of the device's manufacturer, doctors need to rely on the measured data to provide correct treatment or formulate an observational plan.

While the PPT method has demonstrated high-confidence results in estimating blood pressure with the defined protocol, there is still an applicability problem on the user end. Measuring PPT involves two sensor readings simultaneously: EKG and PPG, as discussed earlier. Even though the latter doesn't require user intervention, the former necessitates the user to close the electrical circuit of their body to perform an EKG. Consequently, the measurement cannot be performed frequently without user intervention, for example, during sleep or physical exercise. In essence, it shares the same measurement limitations as a traditional oscillometric blood pressure device [32].

For assessments that involve standalone PPG sensors, a major limitation is the calibration protocol process. Given the optical nature of the recorded quantity, the readings need to be calibrated with a mechanical reference, especially for applications intended for blood pressure estimation. In the assessment of vasomotor state, where absolute values aren't critical, a protocol should outline which PPG waveform components, besides DCW, need to be evaluated for high-confidence results. This is necessary due to the various waveform morphologies that appear in the real world, apart from the idealized perfect shape.

The same approach is necessary for measurements involving time values, such as left ventricular ejection time (LVET) determination. While the association with the TDW feature yields good results, a common agreement on the onset and ending points is essential. Given that the TDW component comprises a finite disturbance event in combination with different morphologies, a protocol is also required for consistency in interpretation.

Finally, from a numerical standpoint, all the measured hemodynamic markers should be evaluated by a specialist within the proper context. The obtained data must be assessed to determine if the measurements were intended for prevention, treatment evaluation, or cardiovascular disease monitoring.

PHOTOPLETHYSMOGRAPHY FUTURE

An important stride in pulse oximeter technology has already been taken by integrating it into wearable devices. The increased computational power per integrated circuit in these devices holds the potential to enhance the signal processing part of the technology.

The availability of open-source databases containing hemodynamic and physiological data intended for researchers [33,34] will contribute to a proper understanding of PPG technology. In the final analysis, having such resources will help reduce, mitigate, or avoid the discussed drawbacks with a supportive tool.

The existing technological capabilities are poised to elevate PPG technology to clinical grade, enabling it to provide high-confidence measurements. Consequently, cardiovascular markers such as LVET and MPI can be remotely monitored, reducing the need for unnecessary physician office visits. This advancement holds potential benefits for both patients and doctors.

The capability to monitor patients' markers with a higher frequency rate would enhance the evaluation of the efficiency of the treatment plan. Additionally, cardiovascular diseases (CVDs) could be prevented or tracked more effectively, enabling better control and management.

An important assumption pertains to future protocols. The competition to embed hemodynamic markers into wearable devices will likely lead the first entity with proven and credible tracking capabilities to establish standalone protocols. Consequently, the community researching in the respective domain will likely follow the defined rules. However, a potential drawback is that this could trigger disagreements over a common, acceptable protocol, which may delay the accessibility of personalized healthcare [35].

CONCLUSIONS

The age-old noninvasive method, photoplethysmography, holds immense potential for enhancing cardiovascular assessment. However, realizing this potential requires the development of a proper mathematical model that can link and explain all physiological behaviors.

While the interest in PPG surged with the advent of the first smart devices in 2013, no disruptive progress has been achieved since then. Instead, some recurrent topics have been validated rather than proposing novel waveform markers for association with clinical applications. Blood pressure estimation and vasomotor state tracking are currently receiving the most attention, with popular companies piloting projects to integrate them into wearable devices.

Despite current limitations, PPG has shown validity, especially in estimating LVET and in binary detection between hypertensive and normotensive patients. Given the current context of technological advancement, there is optimism that this technology will achieve clinical-grade confidence. Consequently, it is anticipated to become an integral part of human lives by providing easy accessibility to personalized healthcare. This, in turn, will unlock improved health monitoring and contribute to a reduced workload for physicians in handling less critical tasks.

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at rjmilmed@yahoo.com.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers may cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor may not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Editor-in-Chief. The Editor-in-Chief reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at: http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials) are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

– Accessible to the public at no charge;

– Searchable by standard, electronic (Internet-based) methods;

– Open to all prospective registrants free of charge or at minimal cost;

– Validates registered information;

– Identifies trials with a unique number; and

– Includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, a target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The Journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 200 words. Abstracts for original articles should be formatted as detailed in the word form. Titles must not be longer than 120 characters (including spaces). In every article, there must be three to ten pertinent keywords specific to the article yet reasonably common within the subject discipline.

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article. This should be cited as Rom. J. Mil. Med. (year); (vol): [issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related “miniseries” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this

avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of Meta-Analysis and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-Analyses and Systematic Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are suggested to limit to 3000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or diagnosis of unusual cases. Contributions will be reviewed by the Executive Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate.

Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background and description of the disorder of interest together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication, as presented at http://www.ICMJE.org/.

Spelling

The journal uses US spelling and authors should, therefore, follow the latest edition of the Merriam-Webster's Collegiate Dictionary.

Units

All measurements must be given in SI units as outlined in the latest edition of Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations

Abbreviations should be used sparingly and only where they ease the reader's task by reducing the repetition of long technical terms. Initially use the word in full, followed by the abbreviation in parentheses. Thereafter use the abbreviation.

Trade names

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: the title page; the main text file according to the word model.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or an article describing the use of a commercial device, therapeutic substance or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer-review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented according to the word model. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 200 words or less the purpose, basic procedures, main findings, and principal conclusions of the study. If appropriate, divide the abstract with the headings: Background and Aim, Methods, Results, and Conclusions. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to ten keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser – http://www.nlm.nih.gov/mesh/meshhhome.html.

Text

Authors should use the word form in editing the submitted material.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square parentheses in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or fewer; when seven or more list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. Reference to unpublished data and personal communications should appear in the text only.

Use Index Medicus as the style guide for references and other journal abbreviations.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table and legend must be

understandable without reference to the text. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, •, ‣ should be used (in that order) and *, **, *** should be reserved for P-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals, and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication:

Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at rjmilmed@yahoo.com. A cover letter containing an authorship statement should be included. The cover letter should include a statement covering each of the following areas:

– Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author. It is not accepted the idea of equal contribution.

– Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.

– A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects, and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki) and this must be stated.

– For research involving pharmacological agents, devices, or medical technology, a clear Conflict of Interest statement about any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

– For clinical trials, these have been registered in a publically accessible database (see more under 'ETHICAL CONSIDERATIONS (Further Information)' later in these guidelines).

If the above items are not included in the cover letter, manuscripts cannot be sent for review. Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures which should be supplied separately.

The main text file should be prepared using the word model that is to be found on the web page (http://revistamedicinamilitara.ro/wpcontent/uploads/2022/07/Macheta-articole.docx).

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, high-resolution figures (at least 300 d.p.i.) saved as .eps, .jpg or .tif files are required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted Articles

Accepted Articles are published online after final acceptance, and appear in PDF format only.

Proofs

Once the paper has been typeset, the corresponding author will receive an e-mail alert containing the proof of acceptance. It is therefore essential that a working e-mail address is provided for the corresponding author.

COPYRIGHT, LICENSING, AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is submitted.

Abstract: NAFLD (Non-alcoholic fatty liver disease) is a condition of high importance due to its increased prevalence, estimated at 24% of the global population, and its potential progression to advanced liver disease, cirrhosis, and hepatocellular carcinoma. One-quarter of NAFLD patients have NASH (non-alcoholic steatohepatitis), which is histologically described as liver steatosis, inflammation, fibrosis, hepatocyte injury, and death. Metabolic disruptions, such as obesity, diabetes, and dyslipidemia, are considered to have a great impact on the development of NASH. Patients may have NAFLD for a long time before progressing into NASH, which highlights the necessity of periodic imaging and biochemical evaluation of the liver, and also presents an optimal window of therapeutic intervention. The challenge in developing treatment for NASH stems from the slow progression of the disease and the reliance on sequential biopsies as the diagnostic and staging tools. Several non-invasive tests have been developed as potential future alternatives to the current invasive gold standard. This review aims to assess the current available methods of diagnosis and treatment targeting inflammation.

Keywords: NAFLD; NASH; MASH; liver steatosis; liver fibrosis; metabolic syndrome; lanifibranor; obeticholic acid; semaglutide

INTRODUCTION

Non-alcoholic steatohepatitis (NASH) is an advanced form of non-alcoholic fatty liver disease (NAFLD), characterized by liver inflammation and hepatocyte injury, that is progressively evolving due to the accumulation of fat in the liver [1]. NAFLD results from an unhealthy diet and sedentary lifestyle, without high alcohol consumption, and is usually a silent disease before the advanced stages, including cirrhosis, liver failure, and hepatocellular carcinoma [2].

The highest rates of NAFLD were reported in the Middle East (32%) and South America (31%), followed by Asia (27%), USA (24%) and Europe (23%), whereas the lowest rates were in Africa (14%) [3-5]. It is estimated that 25% of the patients with NAFLD are thought to have NASH and a quarter of them are diagnosed with cirrhosis [3-5].

Recent studies show the association between metabolic disruptions and NASH, which is why a new medical terminology has emerged introducing the term MASH as metabolic-associated steatohepatitis. A bidirectional correlation exists between NAFLD and metabolic syndrome (obesity, insulin resistance, and dyslipidemia). Also, patients with type 2 diabetes mellitus (T2DM) have a greater risk of developing NAFLD, with a prevalence estimated at 57.80% (95%CI: 53.88% - 61.62%) [6]. NASH has been reported in 65.26% (95% CI: 51.73%-76.71%) of the patients with type 2 diabetes mellitus, who underwent liver biopsy [6]. In a meta-analysis of more than 8.5 million people from 22 countries, the results show that 80% of the patients with NASH are overweight or obese, 72% have dyslipidemia, and 44% are diagnosed with type 2 diabetes mellitus [3].

The evolution of NASH is non-linear. Some patients progress to cirrhosis, and most of them develop cardiovascular disease, but some patients, even those with fibrosis, may spontaneously regress. Cardiovascular mortality is the most common cause of death in patients with NASH. In contrast, in the U.S., due to decompensated liver disease, NASH is among the top three indications for liver transplantation [6,7].

In a study on patients with liver cirrhosis, secondary to HCV infection or NASH, over 4 years, it was estimated that the annual cumulative risk of HCC (hepatocellular carcinoma) was 2.6% per year in patients with NASH cirrhosis compared with 4.0%

per year in those with HCV cirrhosis [8]. These figures suggest that NASH carries a risk of developing HCC that rivals the risk in patients with HCV-cirrhosis. As such, patients with NASH cirrhosis should be closely monitored for HCC. The decrease in HCV-related transplantation due to the significant effect of the HCV therapies placed NASH and ALD (alcohol-related liver disease) as the most common etiologies of liver disease among liver transplant waiting list registrants without HCC, and NASH is becoming a leading indication in patients with HCC [9].

MATERIALS AND METHODS

This review aims to assess the currently available methods of diagnosis and treatment targeting liver inflammation and fibrosis, named NAFLD, NASH, or similar.

We have selected over 200 English, French, and Romanian studies highlighting information on diagnosing and treating these hepatic diagnoses. For the development of this review, we further selected the articles based on our inclusion criteria, consisting of diagnosis and treatment-focused articles and recently published articles to ensure the current advancements in the field.

Databases such as PubMed, Up-to-date, Medline, and NCBI were used to perform the search using keywords: NAFLD, NASH, liver steatosis, liver fibrosis, and metabolic syndrome. Exclusion criteria were imposed to select the papers, such as the article publication date not exceeding 20 years old, and the publications to be in English, French, and Romanian, addressing the diagnosis and treatment concepts for NASH.

RESULTS

Diagnosis

Identifying a person with NASH can be difficult because neither the diagnosis nor the severity of the liver fibrosis can be predicted based on the risk factors (obesity, insulin resistance, or hepatic steatosis) alone. Accurate fibrosis staging, through biopsy series, is important for diagnosis and mortality assessment. All-cause and liver-specific mortality appear to increase once the F2 fibrosis stage has developed [10]. The risk of liver disease death rises by a factor of 50 to 80 for patients with NASH who have F3/F4 fibrosis, as compared with those who have little or no fibrosis [11,12]. People at risk for NASH, such as overweight or obese patients with metabolic syndrome, elevated alanine aminotransferase (ALT), aspartate aminotransferase (AST), and negative noninvasive results for other causes of liver disease, should undergo further testing. Also, patients with type 2 diabetes mellitus over the age of 45 years are likely to have advanced fibrosis and bad liver outcomes [5].

Before advanced testing for NASH, patients should be thoroughly examined to exclude other causes of steatosis and liver damage and to determine the presence of commonly associated comorbidities (obesity, dyslipidemia, insulin resistance, diabetes, sleep apnea, hypothyroidism, and polycystic ovary syndrome). Excessive alcohol consumption, steatogenic medications, high serum ferritin with increased iron saturation, and viral or autoimmune hepatitis should be excluded [7].

The liver biopsy is an invasive procedure, currently considered the gold standard for diagnosing and staging NASH. Numerous non-invasive methods of diagnosis based on serum markers and imaging tests have been investigated, but their performance is not comparable with the biopsy (Table 1). The need for non-invasive tests has been enhanced to develop new treatments for NASH. Various emerging diagnostic tools are presented in Table 1 [7,13-25].

MRI-PDFF [7,13] (Proton density fat fraction MRI) is the most accurate method of detecting steatosis, whereas MRE [7,14] (Magnetic resonance elastography) is the most accurate tool of staging liver disease, by the "stiffness'' indirectly related to fibrosis. Although availability and costs are a major challenge for clinicians, combining these tests can provide a risk stratification in patients with NAFLD. Non-invasive serum markers include alanine aminotransferase levels, and circulating keratin18 fragment levels and there are also tests such as Fibrometer, microRNA panels, and lipidomic panels. In patients with ALT>70U/L, NASH ALT prediction testing was found to have a 50% sensitivity and 61% specificity [7,15]. Considering the prediction ability of the serum ALT, it should not be used for definitive diagnosis, staging, or evolution of the disease, but only to guide further testing. The NASH Test combines demographic characteristics (age, gender, and BMI), serum markers (ALT and lipids), and alpha-2 macroglobulin, ApoA1, and haptoglobin, with a sensitivity of 33% and a specificity of 94%, indicating that it has a good negative predictive value (NPV) [7,16]. The Fibrometer NAFLD (based on age, weight, fasting glucose, AST, ALT, ferritin, and platelet count) achieves reasonably good results for mild to moderate fibrosis. The positive predictive value (PPV) for correctly identifying F=1 was 84.9%, the NPV was 66.7% and the diagnostic accuracy was 80%. The PPV for F=3 was 74.5%, the NPV was 86.2% and the diagnostic accuracy was 82.1% [17-20]. Fibromax, a diagnostic tool composed of 4 non-invasive biomarker panels, can be used for the diagnosis of steatosis (estimated by the SteatoTest), necrosis and inflammation (evaluated by ActiTest and NashTest-2), and fibrosis (FibroTest). Although it is a well-validated and relatively frequently used test, it may not be accurate for patients with T2DM [21]. OWLiver (Overweight Liver) [16,18] is an alternative for overweight patients and PROC3 (Pro Collagen III) can be used as a differentiating test between steatosis and NASH [24]. NASH Index Score 4 (NIS4) [23] and Enhanced liver fibrosis (ELF) [25] are tools that exclude AST and ALT as parameters in the diagnosis process.

There are two main scoring systems for the biopsy results in NASH. The NAS (NAFLD Activity Score) sums the score of steatosis, lobular inflammation, and ballooning of the liver cells. The score (0-8) is not diagnostic. It was designed to evaluate the histological changes in seriate biopsies. It is usually interpreted by adding the fibrosis score (0-4) (Table 2) [7,26-27]. Another available score is SAF

(Steatosis, Activity, and Fibrosis). By evaluating 1000 biopsies, there was an excellent concordance between the two scores in determining the definite NASH, whereas 84% of the NAS borderline biopsies (3-4), were identified by SAF score as NASH [7,26-27].

Table 1: Non-invasive methods of diagnosis [7,13-25]

Test	Parameter measured	Observations
MRI-PDFF [7,13] (Proton density fat fraction magnetic resonance imaging)	steatosis	most accurate method of detecting steatosis
MRE [7,14] (Magnetic resonance elastography)	liver stiffness	most accurate modality of staging liver disease, by the ''stiffness'' indirectly related to fibrosis.
NASH Test [7,16]	age, sex, height, weight, serum triglycerides, cholesterol, a-macroglobulin, apolipoprotein A1, haptoglobin, gamma-glutamyl transpeptidase (GGT), alanine aminotransferase (ALT), aspartate aminotransferase (AST) and total bilirubin	sensitivity of 33% specificity of 94%
FibroMeter VCTE [17-20] (Vibration Controlled Transient Elastography)	Fibrosis, liver stiffness Combines TE (transient elastography) with biochemical markers (age, sex, AST, urea, platelets, prothrombin time, GGT, and alpha2-macroglobulin)	shows good results for mild to moderate fibrosis By combining biochemical markers with imagistic results it increases the accuracy
Fibromax [21]	Combines 4 non-invasive biomarker panels SteatoTest, ActiTest, NashTest-2, and FibroTest	affordable and simple score, but it may not be accurate for patients with T2DM
FNI [22] (The Fibrotic NASH Index)	fibrosis AST, high-density lipoprotein cholesterol, and hemoglobin A1c	accurate, affordable, and simple score for patients with fibrotic NASH
NIS4 [16,18,23] (NASH Index Score 4)	miR-34a-5p, alpha-2 macroglobulin, YKL-40, and glycated haemoglobin A1c	Identifies at-risk patients, defined as [NAS] ≥4 and fibrosis stage ≥2 on biopsy
OWLiver [16,18] (Overweight Liver)	extensive analyses of triglycerides panel by high-performance liquid chromatography and mass spectrometry	Used for individuals with BMI>25 kg/m^2
PROC3 [18,24] (Pro Collagen III)	Pro collagen III	Differentiates steatosis from NASH
ELF [18,25] (Enhanced liver fibrosis)	fibrosis hyaluronic acid, procollagen III, and tissue inhibitor of matrix metalloproteinase 1 (TIMP-1)	stages liver fibrosis independently of AST, ALT elevations

Treatment

The main pathogenic processes identified in NASH are metabolic stress, inflammation, and fibrosis. Pharmacologic agents that target these key mechanisms are being investigated in clinical trials [2].

Due to the lack of pharmacological therapies for NASH, lifestyle modifications remain the main intervention for mitigating histological impairment. Weight loss appears to bring the highest benefit.

Usually, the recommendations include 5-10% weight reduction for obese and overweight patients, physical activity, and a Mediterranean diet. Ultra-processed foods and drinks, fructose-enriched beverages, and alcohol should be avoided. In addition, associated comorbidities (T2DM, dyslipidemia, POS) should be treated [1,26].

Vitamin E, pioglitazone, and statins are available options for patients with NASH. Studies have indicated the role of vitamin E in the reduction of steatosis and fibrosis [28,29]. Pioglitazone, a treatment used for type 2 diabetes mellitus, has been reported to significantly reduce fibrosis in NASH patients. In addition, statins have been tested on NAFLD/NASH patients, with substantial results in improving steatosis and fibrosis [30].

The PIVENS trial focused on NASH patients without diabetes, who were randomly assigned to one of three groups (pioglitazone 30 mg daily, vitamin E 800 IU daily, or placebo). The vitamin E group had a significantly higher rate of histology improvement than the placebo group 43% vs. 19%, but pioglitazone did not meet the primary outcome [31]. Based on several studies, there is a variability in treatment response for vitamin E supplementation. Genetic variations in haptoglobin and FADS1/FADS2 (fatty acid desaturase 1 and 2) have been suggested to interfere with the treatment response, determining whether a patient will show histological improvement or not [32].

Many new potential therapies for NASH are currently studied in phase III trials. The pan-PPAR agonist (Peroxisome proliferator-activated receptors), lanifibranor, has completed the phase IIb trial with 247 participants, the results show a reduction in the SAF activity score (> 2 points), with no increase in fibrosis, achieved by 49% of patients compared with 27% on placebo. The results were significantly higher among those who received 1200 mg of lanifibranor vs. the group with 800 mg dose. In the lanifibranor groups, there was an improvement in liver enzyme levels and also in the majority of lipid, inflammatory, and fibrosis biomarkers [33]. There is an ongoing phase 3 study conducted to evaluate the safety and efficacy of lanifibranor compared to placebo on 1000 participants

with NASH and liver fibrosis histological stage F2 or F3 [34].

The GLP-1 receptor agonist, semaglutide, has also completed a 72-week, phase 2 trial (NN9931-4296) with 320 participants, showing resolution of NASH and no worsening of fibrosis for 59% of patients, in the 0.4mg group, and 40% of patients, in the 0.1mg group, compared with 17% on placebo. The percentage of participants with an improvement in NAS score was 82.9% in the 0.4mg group compared with 43.8% on placebo [35]. A phase 3 study, ESSENCE (The Effect of Semaglutide in Subjects With Non-cirrhotic Non-alcoholic Steatohepatitis), was initiated in 2021 and the interim results are expected in 2024 [36].

Table 2: NAS score and fibrosis staging (adapted from [7,27])

Characteristic	Score
Steatosis	<5%=0 5-33%=1 (mild) 33%-66%=2 (moderate) >66%=3 (severe)
Lobular inflammation	No foci = 0 <2 foci per 200 field =1 2-4 foci per 200 field =2 >4 foci per 200 field = 3
Ballooning	None = 0 Few = 1 Many cells = 2
NAS Score	0-8
Fibrosis	None = 0 Mild = perisinusoidal or periportal (stage 1) Moderate = perisinusoidal and portal/periportal (stage 2) Severe = bridging fibrosis (stage 3) Cirrhosis = stage 4

For liraglutide, also a GLP-1 analog, a multicenter, double-blinded, randomized, placebo-controlled phase 2 trial (the LEAN trial) has demonstrated histological resolution of non-alcoholic steatohepatitis and a significant effect on liver fibrosis after 48 weeks of treatment. In addition, the comparison between pioglitazone and liraglutide showed better results for the latter [37-39].

Obeticholic acid, a selective FXR (farnesoid X receptor) agonist, approved by the FDA in 2016 for primary biliary cholangitis, previously completed a phase III trial (REGENERATE) on 1968 NASH participants with fibrosis F2–F3. The results show that the drug improved the fibrosis score by at least one stage, but did not meet the endpoint of NASH resolution [40]. The FDA rejected the approval of obeticholic acid for NASH in May 2023, based on the modest benefits that did not outweigh the risks.

A phase IIb randomized study of the efficacy and safety of Namodenoson, an A3 adenosine receptor (A3AR) agonist, in the treatment of NASH is ongoing. Previous trials on Namodenoson showed normalization in ALT and AST levels after 12 weeks of treatment [41].

Pegozafermin, a long-acting glycopegylated fibroblast growth factor 21 (FGF21) analog, showed improvements in fibrosis in a phase 2b trial (ENLIVEN). The fibrosis improvements occurred in 7% of the placebo group and between 22-27% in the pegozafermin groups (22% with 15 mg – pegozafermin, 26% on 30 mg dosage, and 27% on 44 mg dosage). The NASH resolution was 2% in the placebo group, 37% in the 15mg pegozafermin group, 23% in the 30 mg pegozafermin group, and 26% in the 44 mg pegozafermin group. The study completion date is estimated around September 2024, demonstrating favorable prospects for advancing to phase 3 [42,43].

Oxidative stress and the formation of reactive oxygen species (ROS) are often associated with the progression of NAFLD to NASH. Excessive ROS formation impairs insulin sensitivity and inflammatory responses. The release of pro-inflammatory molecules and uncontrolled ROS production in many cells is partially the result of TAGE (toxic advanced glycation end-products) and receptor for AGEs (RAGE) interactions [44,45]. Hyperglycemia contributes to the production of advanced glycation end-products (AGEs), especially AGEs formed from glyceraldehyde (GA), which are highly cytotoxic, damaging the hepatocytes. AGEs and TAGE were measured in a study of 66 patients with histologically confirmed NASH without cirrhosis, 10 with NAFL, and 30 control subjects [46]. The TAGE levels of NASH patients were significantly higher than those with NAFL. Ultra-processed foods with a high content of sugar (fructose-enriched or sugar-sweetened drinks) and dietary AGEs have been suggested to contribute to the development of obesity, metabolic syndrome, and the progression of NAFLD/NASH when consumed excessively [47].

Antioxidants such as pentoxifylline (PTX), silybin, resveratrol, and vitamins A, C, and E are used in clinical trials against NAFLD and NASH [47].

PTX treatment with three divided doses of 400 mg for one year improved hepatic histological activity. NAS ≥ 2 improved by (75%) in the PTX group and 30% in the placebo group, but there was no impact on fibrosis [48]. Also, another study on PTX (1200 mg/day) and fenofibrate showed a beneficial effect on indirect biochemical markers of hepatic fibrosis. After 24 weeks, the association of fenofibrate and PTX resulted in reduced liver fibrosis and stiffness, insulin resistance, and inflammation [49]. The combined administration of PTX (1200 mg/daily) and metformin (1500 mg/ daily) for six months reduced AST, and ALT levels and improved

insulin resistance in patients with NASH [50]. A meta-analysis based on 5 RCT on patients with NAFLD/NASH reported that PTX treatment could reduce glucose serum levels, liver transaminases, body weight, and TNF-α levels and also improve NAS and fibrosis scores [51]. Another study used combinational therapy (PTX+Vitamin E) and the results showed regression of fibrosis compared to vitamin E alone [52]. In a phase 2 study, pentoxifylline (PTX) alone significantly improved steatosis, lobular inflammation, and liver fibrosis and was well tolerated [53]. Therefore, PTX can be used along with other drugs as an adjuvant for metabolic diseases.

A phase 4 study conducted on 102 NASH patients divided into 3 intervention groups (PTX, vitamin E, and ursodeoxycholic acid) measured the levels of several serum markers (AST, ALT, IL6, and CCL2/ MPC-1, albumin, total bilirubin, direct bilirubin, total cholesterol, triglyceride, LDL, HDL) for 3 months [54].

In 2017 a study [55] based on an experimental rat model of NASH demonstrated for the first time that the combination of SAMe (S-Adenosyl-L-Methionine) and DLPC (Dilinoleoylphos-phatidylcholine), two physiologic antioxidants, significantly opposed liver injury generated by fat excess.

Numerous studies on hepatoprotective drugs, probiotics, and antioxidants, such as Siliphos—Selenium—Methionine—Alpha Lipoic Acid, omega-3 fatty acids, and vitamins A, C, and E, are currently ongoing [47,52,56-58].

CONCLUSION

The treatment for non-alcoholic steatohepatitis is, unfortunately, an unmet need. At present, there are no FDA-approved therapies for this condition, and the same holds for the EU. Considering the increasing prevalence and the risk for progression toward advanced liver disease, cirrhosis, and hepatocellular carcinoma, there is a major demand for reliable non-invasive biomarkers and specific therapy. In addition to healthy diet and exercise, many new pharmacological agents, such as lanifibranor, semaglutide, and obeticholic acid are being studied. Antioxidants as well are used in clinical trials against NAFLD and NASH.

Despite the clinical and epidemiological significance, the accurate diagnosis, monitoring of the diagnosed patients, and available licensed treatments remain the challenges of NASH.

Abstract: A multinodular and vacuolating neuronal tumor (MVNT) is a rare non-malign central nervous system tumor. The cerebral cortex of young to middle-aged adults is affected and seizures and focal neurological deficits could reveal it. Despite being considered a low-grade tumor, MVNT can be challenging to diagnose and manage due to its histopathological similarities to other neuronal tumors. The limited number of reported cases makes it difficult to establish definitive guidelines for treatment and follow-up. Given the relatively recent discovery of MVNT, there is a need for further research to better understand its pathogenesis, optimal treatment and long-term strategies. Furthermore, studying MVNT can contribute to the broader understanding of brain tumor biology and the intricacies of tumor heterogeneity. This paper explores the challenges and perspectives surrounding MVNT to improve clinical decision-making and patient outcomes. Based on the present narrative review, advancements in diagnostic technologies have shown promise in addressing the challenges associated with diagnosing MVNTs. Liquid biopsy is an innovative and non-invasive diagnostic tool that analyzes biomarkers to provide information about tumors, and radiomics is a method that extracts quantitative data from medical images to provide detailed insights into tumor characteristics. Such innovative diagnostic technologies are important because they have the potential to significantly improve the current diagnostic landscape for MVNTs, allowing for earlier detection, accurate classification, and personalized treatment strategies.

Keywords: multinodular and vacuolating neuronal tumor; radiomics; liquid biopsy; diagnostic methods; histological examination; FDG-PET/CT; immunohistochemistry

INTRODUCTION

First described in 2013, multinodular and vacuolating neuronal tumor (MVNT) was classified as a benign ganglion cell grade I tumor, potentially associated with seizures, with a specific molecular marker, as outlined in the WHO 2016 and 2021 classification [1-3]. The discovery of MVNT is often accidental, and it is frequently asymptomatic [1,2]. Studying MVNT is of utmost significance in neuro-oncology. Understanding the molecular mechanisms underlying the development and progression of MVNT can provide insights into potential therapeutic targets and treatment strategies.

Typically identified in adults, MVNTs seem to appear during neurogenesis and present as subcortical clusters of nodular lesions within the cortex and superficial subcortical white matter [4]. Structure abnormalities in the cortex may be present with it [4,5]. Initially classified as either neoplastic or malformation, recent research on MVNTs emphasizes their stable nature over time, suggesting that they are “leave me alone” lesions with minimal changes in volume, thus underscoring the potential for less frequent imaging surveillance [6,7]. Whether the nodules of vacuolar neurons are a definite neoplastic transformation or aberrant development is still up for debate [6]. Overall, these insights contribute to a nuanced understanding of MVNTs, highlighting the complexities and diagnostic considerations surrounding these distinct neuronal tumors. Moreover, the purpose of this research is to shed light on the challenges and perspectives surrounding MVNT.

MATERIALS AND METHODS

A narrative review was conducted through five electronic databases (PubMed, CINAHL, Google Scholar, Cochrane, Web of Science/Clarivate), using as keywords “multinodular and vacuolating neuronal tumor” AND “diagnosis” OR “pathogen*” OR “imaging” OR “treatment”. All primary and secondary reports found from the inception of the respective databases up to July 2024 were explored for relevant data. Only papers that addressed explicitly the pathogenesis, diagnosis methods,

and treatment strategies of MVNT were included in the secondary analysis**.**

RESULTS

Based on the literature search, 34 primary and secondary reports were reviewed in detail. The results were classified according to the three areas of interest, i.e., (1) pathogenesis and classification of MVNT, (2) imaging characteristics, and (3) diagnosis and treatment.

Classification and pathogenic characteristics of MVNT

Recent studies have highlighted the challenge of defining and classifying MVNT. Due to its rarity and unique histopathological features, there is ongoing debate within the scientific community regarding its precise definition and classification. Some researchers argue that MVNT should be considered a separate entity from other neuronal tumors due to its distinct morphological characteristics and clinical behavior. On the other hand, some propose classifying it under the umbrella of neuronal and mixed neuronal-glial tumors based on its neurocytic differentiation and immunohistochemical profile.

The purely neuronal tumors in the 2021 WHO classification include multinodular and vacuolating neuronal tumors, gangliocytoma, extraventricular neurocytoma, central neurocytoma, dysplastic cerebellar gangliocytoma, and cerebellar liponeurocytoma.

The mixed glioneuronal tumors include dysembryoplastic neuroepithelial tumor, diffuse glioneuronal tumor with oligodendroglioma-like features and nuclear clusters, ganglioglioma, desmoplastic infantile ganglioglioma/astrocytoma, papillary glioneuronal tumor, rosette-forming glioneuronal tumor, myxoid glioneuronal tumor, and diffuse leptomeningeal glioneuronal tumor [13].

There is a consensus on the need for standardized diagnostic criteria to identify and classify MVNT cases accurately. This would facilitate better communication among pathologists and clinicians, improving management strategies and outcomes for patients with MVNT.

The WHO 2016 classification defines MVNT as a benign ganglion cell tumor with specific pathologic hallmarks [2]. These nodular lesions are typically located in specific brain regions and can present differently across age groups, emphasizing the importance of histopathological examination for accurate diagnosis [1,14,15].

Histopathological analysis of MVNT reveals several distinctive features that aid in their diagnosis and differentiation from other neuronal tumors. One of the hallmark features of MVNT is the presence of numerous vacuoles within the tumor cells. This vacuolation can create a “floating” appearance of the cells and is a critical diagnostic criterion. MVNT typically exhibits a multinodular architecture. The tumor forms distinct nodules, which may vary in size, often surrounded by a gliotic background. Such detailed histopathological analyses are essential for elucidating the distinct features of MVNT and guiding effective clinical management strategies. Nevertheless, no histopathological evidence is available to confirm the diagnosis since only a small percentage of patients with suspected MVNT undergo surgery [10].

Immunohistochemical markers play a crucial role in the diagnosis and classification of MVNT. Various markers have been studied, differentiating MVNT from other tumors with similar histological features, such as dysembryoplastic neuroepithelial tumor (DNT) or ganglioglioma [16,17]. So, immunohistochemistry (IHC) is a crucial tool in the diagnosis and characterization of MVNT, establishing the neuronal nature of MVNT, as seen with positive staining for neuronal markers [18]. MVNT typically shows positivity for several neuronal differentiation markers: NeuN, a neuronal nuclear antigen typically expressed in mature neurons, β-III tubulin, which is highly expressed in neuronal cells and can help confirm the tumor’s neuronal lineage. Synaptophysin, a protein associated with synaptic vesicles, indicates neuroendocrine differentiation and is often used to demonstrate the presence of neurons. Although MVNT is primarily neuronal, some glial markers may also be expressed, reflecting maybe the mixed composition of the tumor. GFAP (Glial Fibrillary Acidic Protein) positivity can indicate a glial component in the tumor. Phenotypic analyses may also include checking for markers that indicate low proliferation rates, which can help distinguish MVNT from more aggressive tumors. Markers like Ki-67 are occasionally assessed but typically show low proliferation in MVNT. The absence of expression for markers associated with high-grade tumors, such as p53 or other markers linked to aggressive histology, reinforces its benign nature [18,19].

Understanding the molecular pathogenesis of Multinodular Vacuolating Neuronal Tumors (MVNT) presents a significant challenge due to the tumor’s unique histological features and clinical behavior. MVNTs are characterized by vacuolated tumor nodules with glial and neuronal differentiation, primarily affecting the cerebrum in adults. The pathognomonic radiological features, such as the soap-bubble morphology and lack of enhancement post-gadolinium injections, provide important clues for differential diagnosis and management strategies [4,11,20,21]. The molecular mechanisms driving its formation and growth remain elusive. Further research is warranted to elucidate the genetic alterations and signaling pathways involved in the development of MVNT. The MAP (Mitogen-Activated Protein) kinase signaling pathway is a critical cellular signaling pathway that regulates various cellular processes, such as growth, proliferation, differentiation, survival, and apoptosis. This pathway is activated by various extracellular signals, including growth factors, cytokines, and environmental stresses. MAP kinase signaling pathway possibly sheds light on targeted therapeutic approaches [22].

Research has identified specific genetic mutations that may contribute to the development of MVNTs. For instance, missense mutations in the BRAF gene or HRAS gene have been linked to the pathogenesis of tumors [22,23]. Vacuolization and neuronal differentiation in MVNTs are characterized by vacuolated neurons. This cellular morphology suggests that disruptions in normal

neuronal differentiation and cellular homeostasis may be due to genetic and epigenetic factors. Investigating the presence of other oncogenes and tumor suppressor genes may provide further insights. In exploring the molecular underpinnings of MVNT, a deeper understanding of its pathogenesis may pave the way for personalized treatment strategies and improved patient outcomes in the future. Like many tumors, MVNTs may exhibit altered vascularization patterns [24]. The tumor microenvironment, including the interaction between tumor cells and surrounding glial cells, immune cells, and extracellular matrix components, plays a crucial role in tumorigenesis [25,26]. Studying these interactions can show how the tumor ecosystem supports MVNT growth and survival.

Table 1: Multinodular and vacuolating neuronal tumor (MVNT) characteristics

Characteristics	Descriptors
Definition [2,3]	Low-grade tumors (grade I) comprising monomorphous neuronal elements in discrete and coalescent nodules, with vacuolar changes both in tumor cells and the neuropil, with a molecular pattern impaling MAPK pathway
Localization [4,9,10]	Parietal lobe, frontal lobe, temporal lobe, occipital lobe, spinal, rare cases of multiple localization, mainly subcortical white matter rare cases with cortical extension
Imaging features [4,11,12]	**Brain CT**- is usually normal or shows a non-enhancing/non-calcifying cortical/subcortical white-matter hypodense lesion, absence of mass effect and edema; **Brain MRI** – intra-axial multiple clustered nodules hyperintense on T2WI and FLAIR; T1WI: small hypointense, homogeneous, and well-defined nodules, some clustered tightly or with a small interface between them, located at the cortical-subcortical junctional side; Abnormal white matter signal surrounding the bubble-like or bunch of grape appearances lesions; No contrast enhancement; Restricted diffusion could be present with high ADC values rare **FDG-PET/CT** brain imaging showed tumor hypometabolism
Histological examination [4,8,12]	No evidence of mitosis, necrosis, or microvessel proliferation; Abnormal clusters and numerous vacuoles within the tumor cells, with different sizes, often surrounded by gliotic tissue; Glioneuronal hamartomas; Hypomyelinated plaque-like nodules extending into the deep cortex;
Immunohistochemical stains [4,8]	Many neuronal cells show weak immunoreactivity for synaptophysin and negative immunoreactivity for neuronal nuclear and neurofilament proteins; Variable background of positive dendritic staining for CD34; Negative for IDH1-R132H mutation antibody; Staining was normal for ATRX and p53; The Ki67 proliferation refraction was very low; GFAP highlighted the reactive astrocytes within the nodules; The vacuolated cells were immunoreactive for synaptophysin, while the fibrillary tumor matrix showed decreased synaptophysin expression compared to the adjacent cortex
Natural evolution [4]	Stable on time, „leave me alone” tumor

MAPK- Mitogen-Activated Protein Kinase; CT – computer tomography; MRI- magnetic resonance imaging; T2 FLAIR – space inversion recovery with fluid attenuation; FDG-PET/CT- fluorodeoxyglucose positron emission tomography/computed tomography; CD34 - transmembrane phosphoglycoprotein encoded by the CD34 gene; IDH1-isocitrate dehydrogenase; ATRX- chromatin remodeling · nucleosome assembly; p53- tumor suppressor gene; Ki67 – a nuclear nonhistone protein present in all active phases of cell cycle; GFAP – Glial fibrillary acidic protein responsible for astroglial cytoskeleton and is not found outside the CNS

Imaging Characteristics of MVNT

Imaging characteristics of MVNT reveal distinctive features that aid in their diagnosis and differentiation from other brain tumors. Described as low-grade lesions primarily found in the cerebrum, MVNT presents as clustered multinodular structures within the cortex and subcortical regions (Table 1). The brain MRI revealed multinodular T2-hyperintense lesions in both the deep cortex and superficial white matter of the frontal lobes or temporal lobes, exhibit a unique soap-bubble morphology, hyperintensity on T2 FLAIR sequences, and minimal or absent contrast enhancement [10,16,27]. Based on the signals from T1, T2, and T2 FLAIR, the nodules have nonhomogeneous signal intensity due to low T1, high T2, and low FLAIR vacuole aspects. Confluent T2/FLAIR hyperintensity overlying cortex was present in some cases [4]. The larger nodules have an inner core that is hypointense, a rim that is hyperintense, and areas with a high signal intensity that connect the nodules. The smaller nodules exhibit a signal intensity that is not uniform, with a central dot of low-intensity [11]. The nodules' periphery shows high signal intensity on FLAIR because of high protein content and neuronal demyelination [11].

Sometimes MR spectroscopy indicates an increase in the choline peak and a decrease in the N-acetyl aspartate peak, and tractography shows a partial disruption of the typical structure caused by the absence of lesional cortical layers [11,28]. No increase in perfusion was observed by perfusion-weighted imaging in another study, and abnormal peaks were not detected by MR spectroscopy [10]. Despite their benign nature, the pathologic hallmark of MVNT, questions their neoplastic or malformative origin and potential association with seizures [29]. Cases of a spinal cord lesion resembling cerebral MVNT of unknown significance were named MVNT-like spinal cord lesions. With intramedullary cystic ovoid nodules within the white matter, some immediately contiguous to the grey matter, this lesion was stable in a follow-up [9,30]. The presence of well-delineated intramedullary cystic ovoid nodules within the spinal cord raises questions about the underlying pathophysiology of MVNT [9]. A comprehensive MR protocol has been suggested to

increase the diagnostic confidence of MVNT [10].

Diagnostic and treatment of MVNT

Despite advancements in imaging and molecular techniques, MVNT can present with various clinical manifestations, posing diagnostic challenges. Usually, MVNT is revealed as an incidentaloma [31]. The clinical presentation is nonspecific, with symptoms such as seizures, headaches, or focal neurological deficits, often mimicking other more common brain tumors or epilepsy syndromes [1,14]. Additionally, the radiological features of MVNT on MRI can be subtle and easily overlooked, leading to misdiagnosis. The lack of specific diagnostic criteria for MVNT further complicates accurate identification, underscoring the need for histopathological examination for definitive diagnosis [16,32]. Biopsy remains the gold standard for confirming MVNT, highlighting the importance of integrating clinical, radiological, and pathological findings to navigate the diagnostic challenges posed by this rare entity in neuro-oncology. Additionally, the classification of MVNT as a benign neuronal tumor, possibly associated with seizures, further complicates the understanding of its neurological manifestations, especially in young patients [33].

Table 2: Immunohistochemical analysis [8,19]

Neuronal markers		Glial markers	
NeuN (Neuronal Nuclei)	A marker for neurons, specifically in post-mitotic neurons. It is widely used to identify neuronal populations in various brain regions.	GFAP (Glial Fibrillary Acidic Protein)	A specific marker for astrocytes. Increased expression is often seen in reactive astrocytes following injury
MAP2 (Microtubule-Associated Protein 2)	A neuron-specific protein that stabilizes microtubules and is important for dendritic structure.	Olig2	A transcription factor and marker for oligodendrocyte precursor cells and mature oligodendrocytes, essential for myelination in the central nervous system
βIII-Tubulin (Tuj1)	A marker commonly used to identify neurons, particularly in developmental studies.	S100	A protein found in astrocytes, used for identifying glial cells
Synaptophysin	A presynaptic vesicle protein, often used to identify synaptic structures and neuronal activity	CD68	A marker for microglia, reflecting macrophage activity in the central nervous system and often used in studies of neuroinflammation.

Distinguishing MVNT from entities such as dysembryoplastic neuroepithelial tumor (DNET), ganglioglioma, extraventricular neurocytoma, and low-grade glioma is sometimes challenging [34]. The bright diffusion sign and absence of cortical involvement could differentiate MVNT from DNET [35]. Moreover, incorporating genetic and molecular analyses can further aid in narrowing down the list of differential diagnoses and confirming the diagnosis of MVNT. Immunohistochemical analysis for neural and glial markers are also helpful (Table 2). Antibodies against neuronal protein HuC/HuD (HuC/HuD), pan-neurofilament (pan-NF), neurofilament 200 KD (NF200 KD), chromogranin, and antibodies against glial fibrillary acidic protein (GFAP), nestin, CD3, CD45, CD68, CD34, human leukocyte antigen-DR (HLA-DR), isocitrate dehydrogenase1 (IDH1), calbindin, parvalbumin, calretinin, Ankyrin-G, p62 and Ki67, BRAF(V600E) enhance diagnostic accuracy [8,19]. Immunopositivity for HuC/HuD and Olig2 proves that MVNT appears during neuronal development [4].

The latest WHO tumor brain classification has classified MVNTs as grade I, and the mitogen-activated protein kinase (MAPK) is considered a molecular marker [3,8]. The MAPK is a key signaling pathway that transmits signals from the cell surface to the nucleus and regulates various cellular processes, including growth, proliferation, differentiation, and survival. Further research in this area, particularly investigating specific diagnostic markers and biomarkers, is warranted to refine the differential diagnosis process for MVNT.

Factors such as tumor size, location, and the presence of associated neurologic deficits can influence treatment strategies and prognosis.

One of the foremost challenges in the preoperative diagnosis of MVNT is the difficulty in distinguishing them from other neoplastic or malformative lesions to avoid unnecessary surgical interventions [36]. The characteristic imaging features of MVNT, such as the subcortical nodular lesions with unique signal properties on MRI, can often be mistaken for more aggressive tumors due to their atypical presentation in younger patients. The rarity of MVNT in young individuals poses a diagnostic dilemma, questioning the

classification of these lesions as true neoplasms or malformative anomalies [22,31,21].

Imaging modalities and treatment strategies play pivotal roles in managing epileptic patients, especially those with drug-resistant epilepsy considered for neurosurgery. Utilizing advanced imaging techniques such as the Harmonized Neuroimaging of Epilepsy Structural Sequences (HARNESS-MRI) protocol and 7-Tesla MRI can aid in identifying previously occult epileptogenic lesions and improving surgical outcomes [37,38]. Additionally, the development of MRI postprocessing techniques and functional imaging modalities like EEG-functional MRI contribute to enhanced sensitivity in lesion detection and focus localization [39].

Surgery is often considered the primary treatment option for multinodular vacuolating neuronal tumors (MVNTs) under several circumstances. If the MVNT is causing neurological symptoms (such as seizures, headaches, or focal neurological deficits), surgical intervention may be necessary to alleviate these symptoms, when the tumor is accessible and can be safely resected without causing significant damage to surrounding brain tissue. Histological confirmation by surgical resection can provide a definitive diagnosis through the histopathological exam, which is crucial for confirming the nature of the tumor and ruling out other possible lesions. However, the precise location of the tumor within the brain can sometimes pose challenges in obtaining a biopsy sample. In such cases, advanced imaging techniques and neurosurgical expertise are indispensable in ensuring accurate sampling for an accurate diagnosis and subsequent management of MVNT. It is essential that surgical decisions are made in consultation with a team of specialists, including neurosurgeons and oncologists, who can evaluate the risks and benefits specific to each patient's condition and tumor characteristics. Functional MRI is as accurate as WADA testing, for determining language dominance [40].

The management of asymptomatic MVNT often involves careful observation rather than immediate intervention. However, a strategy of active surveillance can be appropriate for asymptomatic or minimally symptomatic MVNT. This involves regular follow-up through serial neurological examinations and imaging studies (usually MRI) every 6-12 months**.**

DISCUSSION

Advancements in diagnostic technologies have shown promise in addressing the challenges associated with diagnosing MVNTs. One emerging technology that holds potential is liquid biopsy, an innovative and non-invasive diagnostic tool that analyzes biomarkers (circulating tumor cells and genetic material) from bodily fluids (such as blood, urine, or cerebrospinal fluid) to provide information about tumors [41-46]. Circulating Tumor DNA (ctDNA) from the blood allows for the detection of genetic mutations and alterations associated with MVNT. Liquid biopsy is less invasive than traditional tissue biopsy, making it a more feasible option for patients, especially in complex cases where surgical options may be limited. It allows for repeated sampling without the risks associated with multiple surgical procedures, enabling ongoing monitoring.

Additionally, the development of radiomics, a method that extracts quantitative data from medical images to provide detailed insights into tumor characteristics, could aid in distinguishing MVNTs from other brain tumors with similar radiographic features [44-46]. These innovative diagnostic technologies have the potential to revolutionize the current diagnostic landscape for MVNTs, allowing for earlier detection, accurate classification, and personalized treatment strategies. Furthermore, integrating these technologies into clinical practice could improve patient outcomes and enhance our understanding of MVNT biology.

More studies are needed to elucidate the genetic mutations and molecular pathways involved in the development of MVNT. This would not only provide valuable insights into the underlying mechanisms of this rare brain tumor but also potentially identify novel therapeutic targets. Additionally, clinical research focusing on the efficacy of different monitoring modalities is crucial for optimizing patient outcomes**.**

CONCLUSION

Based on the results of this narrative review, emerging technologies allow for a re-conceptualization of the MVNT diagnosis and treatment. Although data regarding the validity of the new imaging and molecular techniques are still gathering, the fact that WHO includes MAPK as a marker for MVNT indicates the need for further refinement of the differential diagnosis based on molecular explorations in this pathology. The references in the literature related to genetic mutations and alterations associated with MVNT suggest new research directions congruent with the paradigm of personalized medicine.

Abstract: Background: Patients with Lyme disease often suffer from neuro-motor sequelae following Borrelia infection, leading to impairments in balance, posture, and spinal musculoskeletal functionality. This study aims to evaluate the effectiveness of physical therapy in addressing these impairments. Methods: Initial assessments were conducted using the GPS Posture-test System to evaluate static bipodal balance and posture, and BACKFIX Technology for unipedal balance and spinal functionality. Disturbances in balance, postural asymmetries, and a forward-shifted center of gravity were observed. The patient then underwent two 10 sessions (each during two weeks) of computer-assisted physical therapy focused on neuro-muscular movement and balance control. Results: Post-therapy evaluations showed significant improvements in both bipodal and unipedal static balance, segmental and overall body posture, and spinal musculoskeletal functionality. The therapy effectively addressed the postural asymmetries and shifted the center of gravity closer to the optimal vertical posture point. Conclusion: Computer-assisted physical therapy with visual feedback significantly improved posture, balance, and spinal functionality in patients with Lyme disease-related neuro-motor sequelae. This approach facilitated the restoration of muscle coordination and enhanced motor control, aligning with findings from the existing literature.

Keywords: Lyme Disease; Global Postural System; unipedal static balance; BACKFIX; global posture; spine; physical therapy

INTRODUCTION

The specialized literature lacks scientific studies on the functional evaluation and neuromusculoskeletal recovery in Lyme Disease (LD). Approximately 80 articles from the past decade are available in databases, primarily focusing on early detection and antibiotic treatment. No studies provide information on potential methods for functional evaluation or physical therapy-based recovery for musculoskeletal dysfunctions caused by inflammation secondary to Borrelia infection.

LD is caused by the bite of a tick infected with Borrelia. The disease progresses through three stages and can result in multisystem complications. When the nervous system is affected, it is referred to as neuroborreliosis, which may manifest as meningitis, mononeuritis multiplex, or cranial neuritis, including inflammation of the vestibulocochlear nerve [1]. Exclusive involvement of the vestibular system can lead to dizziness and balance instability [2]. Musculoskeletal symptoms can appear at any stage, including early localized infection, often resulting in patients being misclassified into the incorrect stage [3].

We describe motor control and the potential effects of systemic inflammation caused by borreliosis, followed by the stages of assessment and recovery, and the conclusions drawn from these steps.

Although the exact mechanism by which LD causes small fiber neuropathy is unknown, several potential mechanisms of neuronal damage are considered. These include the direct neurotoxic effect of the spirochete, neuroinflammation, and increased autoimmunity affecting the peripheral nervous system (PNS) with subsequent impacts on muscles, joints, and specific post-infection pains. However, a clear causal link between neurological symptoms and Borrelia infection cannot be

established for patients with polyneuropathy/polyneuritis who test positive for Borrelia [4].

Among the genospecies of Borrelia burgdorferi sensu lato: Borrelia burgdorferi sensu stricto (s.s.), Borrelia garinii and Borrelia afzelii, Borrelia burgdorferi s.s. has the strongest potential to damage joints [5]. It is the most common cause of LD in the United States [3, 6], while infections with this pathogen are much less common in Europe [7-9]. The pathogenesis of LD is primarily driven by a strong inflammatory reaction [5], resulting in a perivascular collection of lymphocytes, macrophages, and scattered mast cells in the interstitial tissue, as typically observed in histopathological examinations of severe LD cases [9].

Previous studies have shown that late manifestations affecting the nervous system or joints can appear months or years after the initial infection, presenting symptoms such as fatigue, difficulty walking, posture disorders, and muscle pain. These symptoms are also present in the subject of our study, secondary to the diagnosis of borreliosis [10].

The examination and treatment of patients with motor control disorders are based on theories of motor control that guide the understanding of movement mechanisms [11-14]. In our study, we utilize systems theory as a foundation for clinical applications. Systems theory posits that movement arises from the interaction of various processes, including perceptual, cognitive, and motor processes, as well as the interactions between the individual, the activity, and the environment.

The severity of symptoms observed in all the patients with LD that we have evaluated has led us to pay more attention to this condition. As a result, our study focuses on evaluating and recovering a patient with LD using methods and applications informed by previous scientific studies. We analyzed a patient with sequelae following LD, including postural, walking, and static and dynamic balance disorders, muscle fatigue, changes in balancing synergies, walking base, and the projection of the General Center of Gravity (GCG). We conducted initial and final tests after a series of 10 and 20 sessions of specific physical therapy exercises.

Pioneers in the study of motor control and movement, such as Bernstein and Latash [15-17], along with Charles Sherrington (1857 - 1952), Thomas Graham Brown (1882-1965), and Walter Hess (1881-1973), have significantly contributed to our understanding of joint freedom, redundancy, and muscle-articular synergies. Charles Sherrington contributed to the understanding of inhibition, spinal-muscle connectivity, and the sensory-motor cortex. Thomas Graham Brown researched central movement programming and pattern generation mechanisms. Walter Hess studied the central coordination of the autonomic system and anticipatory motor behavior. Bernstein, recognized posthumously by Western colleagues, demonstrated a central hierarchy of postural control mechanisms and distributed, parallel processing of movement.

Bernstein also participated in developing theories of motor programs, recognizing that understanding neural control of movement requires knowledge of the system's characteristics in response to external and internal stimuli [16]. His distributed model of motor control showed that central commands could produce different motions due to external forces and initial conditions. His student, Mark Latash, furthered this work by demonstrating that synergies evolve to ensure flexible and stable performance in motor activities [17].

Postural control for stability and body orientation in space requires a complex interaction between the musculoskeletal and neural systems. This includes joint amplitudes, intersegmental biomechanical relationships, muscle physiology, spinal flexibility, neuromotor processing, synergies, perceptual and sensory processes, and their central integration.

Research has concluded that postural control is not managed by a single system but depends on various intrinsic and extrinsic factors [18]. Initial studies highlighted the importance of maintaining the center of mass (COM) within certain limits for static posture. However, subsequent studies demonstrated that stability limits are not fixed and vary with individual characteristics or actions undertaken. When recovering balance, individuals tend to restore COM disturbances rather than segmental alignment disturbances, suggesting that COM is a key variable controlled by the central nervous system during postural control.

Further studies have shown that analyzing the relationship between the center of gravity (COG) and the center of pressure (COP) provides a better picture of stability [19-24]. Their interaction has been considered and used to measure and estimate posture control effectiveness in our study.

As actions have both stability and orientation components, and certain actions prioritize orientation over stability, research by Shumway-Cook & McCollum [25] and Horak & Macpherson [26] has demonstrated that stability and orientation vary with each action. The body can behave like an inverted pendulum, employing various strategies (ankle, hip) for both static and dynamic balance [21].

Bernstein's assertion that "Movement coordination is the process of mastering the redundant degrees of freedom of a mechanism in motion" [16] encapsulates the essence of motor control theories used in our study.

Equilibrium

While bipedal standing is characterized by minor postural imbalances, dynamic balance involves the integration of sensory information from the visual, vestibular, and proprioceptive systems in conditions of postural instability.

There are several theories about how sensory organization adapts to a changing environment, with two primary ones being: the intermodal theory of sensory organization by Stoffregen and Riccio [27], which posits that all sensory systems equally and continuously contribute to postural orientation; and the sensory weighting model, which suggests that the central nervous system adjusts the importance of each sensory system based on their accuracy for orientation and postural stabilization.

Torres and Oviedo [28] examined the structure and organization of muscle synergies for balance control, highlighting that a muscle can contribute to multiple synergies, each with a unique role. They demonstrated that muscle synergies can be continuously modulated by feedback signals to create postural adjustments, indicating that the central nervous system uses both pre-programmed synergies and continuous feedback control to regain stability.

Nashner et al. [29] investigated the selection of sensory information by the CNS for postural control by designing a dynamic platform with a moving visual wall to study sensory interactions in maintaining posture and balance. This approach allowed for the measurement and recording of posture and balance under various conditions.

Several studies on normative values using static platforms have examined the performance of normal subjects under varying sensory information conditions [29-33]. These studies have shown that adults and children over seven years old (the age of vestibular maturation) maintain balance well under all conditions of sensory disturbance.

The inability to maintain a stable static posture has significant functional consequences in neurological pathologies. It necessitates using the arms and hands for balance, detracting from daily activities [34-38]. Moreover, postural instability and the inability to stand on one leg for more than six seconds increase the risk of falls threefold.

Springer's 2007 study [39] showed that balance disorders are prevalent in patients with specific diseases or traumas, particularly head injuries, peripheral neuropathies, or acquired neurological conditions. Neurological pathologies can disrupt one of the postural control strategies (e.g., loss of pre-programmed synergies) while leaving the other (continuous feedback control) intact, necessitating complementary studies to distinguish between these aspects and propose specific solutions.

For the main types of static/dynamic balance (postural control/anticipatory and reactive postural control), numerous clinical tests measure performance, including the unipedal stance and computerized posturography. Our study used such tests to assess the patient's condition at the beginning and end of the recovery program.

Unipedal standing is a highly challenging situation for humans and allows researchers and clinicians to assess the effects of aging, disease, trauma, and the influence of multiple sensory systems. The single-leg stand test, which requires minimal equipment, measures balance aspects and shows abnormal values in conditions such as peripheral neuropathies and intermittent claudication. [35,36]

Various studies demonstrated the importance of maintaining unipedal posture and balance by examining corticomuscular coherence between the ankle joint and the sensorimotor cortex. This study showed that the sensorimotor cortex is directly involved in postural control during unipedal standing, compensating for high postural demands due to the low support base. Normative values in the literature indicate a significant decrease in unipedal stance time with age and pathology [40, 41].

Alain Berthoz et al. [20] demonstrated that during complex movements, the head is intermittently stabilized under gaze and fixation control, allowing it to act as an inertial guidance platform for controlling multisegmental movements. The otolithic organs, the saccule, and utricle, detect the linear accelerations of the head and provide a gravitational reference used not only to correct posture but also for perceptual actions requiring spatial orientation, including mental map rotation based on sensory information from all senses.

Merton's Servo-Control Hypothesis

The interaction between motor and sensory processes is bidirectional, and the importance of sensory information for motor control was established many years ago. The traditional feedforward and feedback control mechanisms could not fully explain the coactivation of the alpha-gamma muscle loops, necessitating alternative theories such as the equilibrium point hypothesis and the hierarchy of synergies to explain how correct posture is maintained during external destabilizations [42].

Merton proposed a model that adjusts the equilibrium point, where the CNS controls both speed and position during rapid segmental movements. Degenerative, infectious, and metabolic diseases have disrupted the transmission of sensory information from the periphery to the CNS, affecting the parameters and components of posture and movement control. Disorders of nerve conduction from proprioceptors to the brain, as seen in neurological or diabetic patients, result in significant balance issues, making it difficult for patients to stand upright with their eyes closed on a static plane [42].

Posture, a term introduced by André Bregegère in 1955 [43], is defined as a momentary attitude or body position [44]. It involves the synergistic and coordinated action of the musculoskeletal system and the central and peripheral nervous systems to maintain body stability, balance, and constant relations between body segments and the environment [45-47]. Correct posture involves the alignment of all joints, and any misalignment can lead to muscle-joint imbalances [48].

Maintaining postural stability requires the co-participation and complementarity of actions from all support components, followed by motor actions (balancing, distribution of motor control tasks), which can be synchronous or asynchronous, simultaneous, or alternating depending on the demands [44,49]. Optimal body alignment in an upright position involves:

Head: Maintained by neck muscles. Insufficiency or habitual forward tilt increases muscle demand.

Trunk: Tends to fall forward due to its weight and the head's weight, counteracted by vertebral muscles.

Shoulders: The scapular belt and upper limbs' weight cause the shoulders to fall and scapulae to separate from the spine, counteracted by shoulder girdle muscles.

Pelvis: Key to maintaining correct posture. Anteversion is balanced by gluteal and posterior thigh muscles, whose hypotonia causes anterior trunk tilt. Retroversion is balanced by rectus abdominis, obliques, and iliopsoas muscles, whose hypotonia causes posterior tilt.

Lower limbs: Stability is ensured by plantar flexor muscles and triceps surae, especially the soleus [45].

Postural defects can lead to fatigue, muscle strain, and pain in later stages, potentially affecting vital organs, particularly in the abdominal region. Our study integrates current scientific conclusions and hypotheses to address parameters affecting motor control and static and dynamic postural control in our subject, considering the literature review.

Motor control theories are inherently unfinished, always allowing room for new information from recent studies on normal and pathological brain and PNS functioning. Neuroscientists identify the scientific basis for movement disorders, while clinicians develop applications of this research, as theories are considered more or less useful based on their problem-solving efficacy for patients with movement disorders.

In this context, we present a study where a patient with Lyme disease sequelae is compared to literature findings regarding posture, balance, and neuromuscular control of movement. Previous works by Schor D, Schor V et al.[50-52] introduced the BACKFIX Method, used for spine functional impairments in preventive care. This study evaluates its application to a complex disease like LD, characterized by neurological symptoms affecting balance, walking patterns, general movement control, and muscle strength imbalance.

We demonstrate the patient's condition evolution using physical therapy with visual feedback on the rectangular force-amplitude model. Improvements in agonist-antagonist cooperation lead to enhanced muscle strength, functional muscle-joint balance of the spine, posture, and walking pattern. The patient exhibited muscle cramps in the calf and foot, pronounced thigh flexor fatigue during walking, insecurity in unipedal support, jerky walking with a wide support base, and reduced standing time in unipedal support.

MATERIALS AND METHODS

We performed the following measurements:

- Computerized somatoscopic examination
- Forces, amplitudes, and mechanical work on the supporting muscles of the trunk, enabling a computerized muscle-articular evaluation of the trunk
- Bipodal static balance - stabilometry
- Unipedal static balance

We utilized the GPS System (Global Postural System) for computerized somatoscopy and computerized static bipodal balance tests, provided by UNEFS Bucharest (University of Physical Education and Sport from Bucharest), and the Ergocontrol System for musculo-articular functionality tests of the spine using the Backfix Method, technology provided by Medisport Company.

An initial evaluation and two intermediate evaluations were conducted. For the static one-legged balance test, we measured the hold time while standing on one leg. An initial evaluation and two intermediate evaluations were conducted. For the static one-legged balance test, we measured the hold time while standing on one leg

RESULTS

Initial Assessment Results

Computerized Somatoscopy Test

Front:

- Right shoulder slightly lowered and rotated anteriorly
- Left shoulder slightly raised
- Right hip slightly lowered
- Left hip slightly raised

Profile:

- Abdominal hypotonia with increased lumbar curvature
- Projection of the GCG (general center of gravity) 11 cm anterior to the normal position

Back:

- Left shoulder blade normally positioned
- Right shoulder slightly lowered and rotated anteriorly
- Left shoulder slightly raised
- Right hip slightly lowered
- Left hip slightly raised

Evaluation of the Muscle-Articular Functionality of the Spine

The results of the computerized musculo-articular measurements regarding the muscular support of the spine are presented in Table 1. The movements were performed with difficulty and were jerky, which is characteristic of the neurological sequelae of the condition.

Table 1: Initial muscle-articular evaluation (3.02.2023)

Test segment	F(daN)	L(cm)	Lm(J)
Direct – abdominal Indirect – lumbar	5.5	26	14.47
Direct- Scapular girdle ½ anterior, thorax anterior Indirect – anterior and posterior muscle groups of the trunk	9.31	49	45.45
Direct- Scapular girdle posterior ½ of the trunk Indirect – anterior and posterior muscle groups of the trunk	8.47	39	32.85

Resources and methods used in recovery

The recovery protocol involved 20 sessions of exercises utilizing visual feedback on force-amplitude curves, performed on the Ergocontrol System. This protocol aimed to restore agonist-antagonist cooperation within muscle groups and chains responsible for global body posture while also focusing on strength enhancement through movement control exercises targeting deficient muscle groups and chains.

Each session included walking exercises designed to integrate the improvements from the neuro-muscular movement control exercises, to enhance the walking pattern.

Results After 20 Recovery Sessions

There was a noticeable improvement in overall body posture and a tendency towards optimizing the indices of musculo-articular functionality of the spine. The results from the intermediate evaluations demonstrate progressive improvements in all measured parameters, as detailed in Tables 2 and 3.

Table 2: Intermediate muscle-articular evaluation (27.02.2023)

Test segment	F(daN)	L(cm)	Lm(J)
Direct – abdominal Indirect – lumbar	15.6	41	64.93
Direct- Scapular girdle ½ anterior, thorax anterior Indirect – anterior and posterior muscle groups of the trunk	181	61	110.29
Direct- Scapular girdle posterior ½ of the trunk Indirect – anterior and posterior muscle groups of the trunk	179	58	104.37

Table 3: Intermediate muscle-articular evaluation (26.03.2023)

Test segment	F(daN)	L(cm)	Lm(J)
Direct – abdominal Indirect – lumbar	20.8	49	103.5
Direct- Scapular girdle ½ anterior, thorax anterior Indirect – anterior and posterior muscle groups of the trunk	21.5	66	140.7
Direct- Scapular girdle posterior ½ of the trunk Indirect – anterior and posterior muscle groups of the trunk	213	56	118.2

The evolution of the somatic functionality of the trunk

Spine Pathology and Accident Risk Scale:
- < 0.50 = High Risk
- 0.50-0.75 = Medium Risk
- 0.75-0.95 = Low Risk

Initial Personal Levels:
- Lumbar: High
- Antero-posterior Thoracic: Medium

After Two Series of 10 Physical Therapy Sessions:
- Lumbar: Medium
- Antero-posterior Thoracic: Low

Chart number 1 illustrates the progress in muscle-articular functionality indices of the spine, specifically Thoracic Antero-posterior and Thoraco-lumbar, as assessed by Test 2 and Test 3. These improvements are also evident in the overall body posture, with notable

enhancements in the static balance and the projection of the GCG (see Figure 1).

Table 4: Segmental and intersegmental muscle-articular functionality ratios of the spine

Segmental and inter-segmental ratio	Optimal values	Personal values 03.02.2023	Personal values 27.02.2023	Personal values 26.03.2023
Thoracic anterior - posterior	0.85 - 0.95	0.73	0.94	0.84
Thoraco-lumbar	0.85 – 0.95	0.31	0.59	0.73

Chart number 1: Indices of muscle-articular functionality of the spine - Thoracic antero-posterior and Thoraco-lumbar

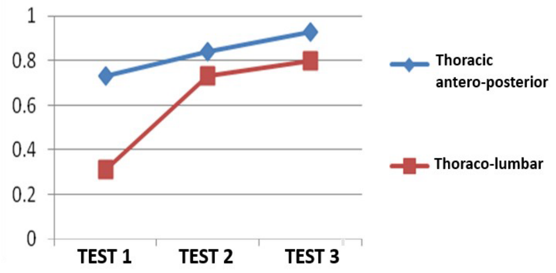

Figure 1: The improvements of the static ballance and the projection of the General Center of Gravity (CGG)

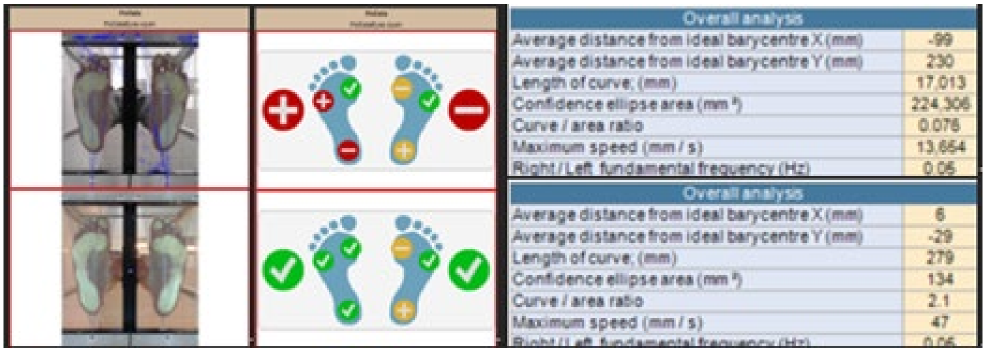

Overall analysis

Average distance from ideal barycentre X (mm)	-99
Average distance from ideal barycentre Y (mm)	230
Length of curve; (mm)	17,013
Confidence ellipse area (mm ²)	224,306
Curve / area ratio	0.076
Maximum speed (mm / s)	13,664
Right / Left fundamental frequency (Hz)	0.06

Overall analysis

Average distance from ideal barycentre X (mm)	6
Average distance from ideal barycentre Y (mm)	-29
Length of curve; (mm)	279
Confidence ellipse area (mm ²)	134
Curve / area ratio	2.1
Maximum speed (mm / s)	47
Right / Left fundamental frequency (Hz)	0.06

Unipedal Balance:
•Initially, unipedal support was impossible.
•After ten sessions, balance time increased to 21 seconds.
•After 20 sessions, the balance time reached 30 seconds.

General Center of Gravity (GCG)

Projection: Figures 2, 3, 4, and 5 depict the improvement in the migration of the General Center of Gravity in four positions: standing with eyes open, standing with eyes closed, facing left, and facing right.

Figure 2: The improvement of the migration of GCG in the position of stand-up face to the right side

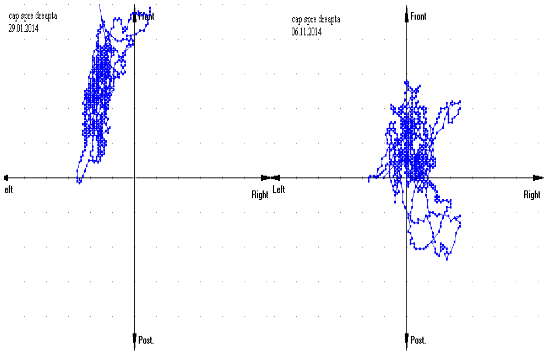

Figure 3: The improvement of the migration of GCG in the position of stand-up face to the left side

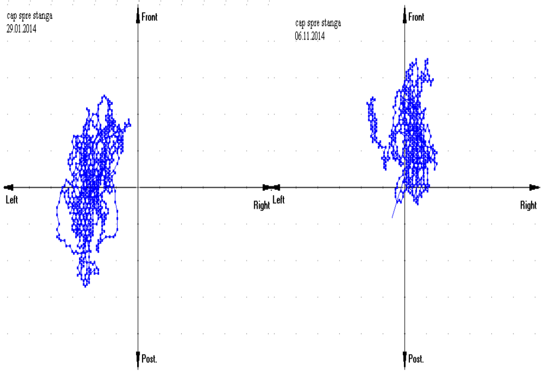

Figure 4: The improvement of the migration of GCG in the position of stand-up eyes closed

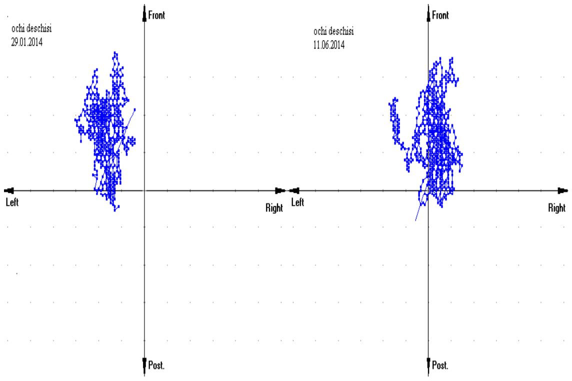

Figure 5: The migration of GCG improved in the position of standing up and eyes open

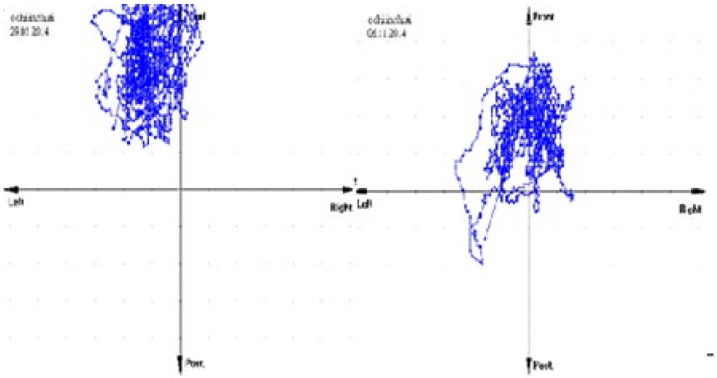

DISCUSSION

The key outcomes and benefits observed after completing two series of 10 physical therapy sessions in the study are presented in the following.

After Two Series of 10 Physical Therapy Sessions:
- Increased muscle strength and joint amplitude at the shoulder girdle.
- Continued need for abdominal muscle strength improvement to balance spinal muscle support.
- Enhanced muscle-articular functionality indices for the Thoracic Antero-Posterior and Thoraco-Lumbar regions, showing improvement from 0.73 to 0.84 and from 0.31 to 0.73, respectively.
- Balance time in the unipedal position with eyes open increased from 0 to 30 seconds.
- Improved gait from a jerky, insecure pattern to a smooth, balanced walk.
- During computerized somatoscopic evaluation, overall body posture improved, with the anterior projection of the CGG reducing from 11 cm to 5 cm from the normal projection.

The BACKFIX Method:
- Led to improved posture by optimizing muscle-articular functionality indices of the spine.

Visual Feedback on Force-Amplitude Patterns:
- Restored agonist-antagonist cooperation, positively affecting gait and balance motor control.

Optimized Functional Musculo-Articular Balance:
- Resulted in visible improvements in posture and walking pattern.

Risk Reduction:
- The risk of spinal pathology and accidents improved, moving from medium to low risk, with enhanced muscle chain synergies supporting proprioceptive and sensory system integration in unipedal stance.

The observed benefits from targeted physical exercises confirm previous studies on the uniqueness of bipodal and unipedal stance control, inter-segmental coordination, and the antigravity function of the leg extensors. Most cases of LD resolve after one course of therapy, although some patients experience gradual symptom relief even after treatment ends; therefore, follow-up assessments are recommended 3 months post-therapy. In some cases, symptoms persist despite antibiotic treatment, leading to the term "antibiotic-refractory LD", defined as persistent synovitis lasting more than 1 month after two four-week oral antibiotic courses or more than 2 months after intravenous ceftriaxone treatment [53].

Untreated arthritis may eventually resolve on its own, but it can persist for years, with some cases of LD lasting 7-8 years [54,55]. Potential treatments for patients with post-arthritis LD include non-steroidal anti-inflammatory drugs (NSAIDs), disease-modifying anti-rheumatic drugs (DMARDs), biologic agents, intra-articular steroids, and arthroscopic synovectomy [55,56].

The strengths of this study lie in its focus on the functional evaluation and rehabilitation of patients with Lyme disease-related neuro-muscular issues, an area with limited prior research. The use of computer-assisted physical therapy, employing technologies like the GPS Posture-test System and BACKFIX Technology, allowed for a precise and objective assessment of balance and posture, leading to significant improvements in the patients. These technologies facilitated a more thorough understanding of musculoskeletal impairments and offered targeted interventions that improved both static and dynamic balance, posture, and muscle coordination.

However, some limitations must be noted. The rehabilitation was conducted on one patient, and this limits the generalizability of the results. Additionally, the long-term sustainability of the therapy outcomes remains uncertain, and further follow-up studies are needed to verify the persistence of improvements beyond the immediate post-treatment period. Another limitation is the lack of control, which would have strengthened the validation of the study's findings.

Future research in this domain should focus on expanding the sample size and incorporating control groups for comparative analysis. Long-term studies are also crucial for understanding the chronic impact of rehabilitation techniques. Finally, integrating more advanced technologies, such as virtual reality or machine learning algorithms for personalized therapy adjustments, could further enhance patient outcomes in neuro-muscular recovery for Lyme disease.

CONCLUSION

This study demonstrates the effectiveness of computer-assisted physical therapy using technologies such as the GPS Posture-test System and BACKFIX Method in addressing the neuro-muscular and postural impairments associated with Lyme disease sequelae. Patients exhibited significant improvements in static and dynamic balance, posture, and musculo-articular functionality after completing two series of physical therapy sessions. The visual feedback provided during therapy sessions played a crucial role in restoring agonist-antagonist cooperation and enhancing motor control.

In conclusion, targeted physical therapy combined with advanced postural assessment technologies offers an effective means of improving functional recovery in Lyme disease sequelae patients, supporting their overall motor control and quality of life.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. The funders had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript; or in the decision to publish the results.
